My Work

The $t\bar{t}$ Forward-Backward Asymmetry A_{FB}

What is A_{FB} ?

- ▶ Consider $q\bar{q} \rightarrow t\bar{t}$
- ▶ top and antitop leave back to back

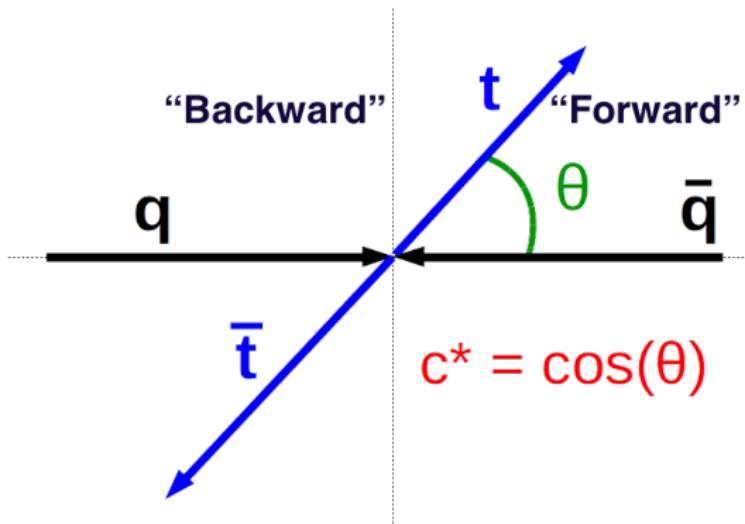

Center of Mass frame

What is A_{FB} ?

- ▶ Consider $q\bar{q} \rightarrow t\bar{t}$
- ▶ top and antitop leave back to back
- ▶ c^* measures whether an event is “forward” or “backward”
- ▶ A_{FB} counts the numbers of forward/backward events and quantifies asymmetry

Center of Mass frame

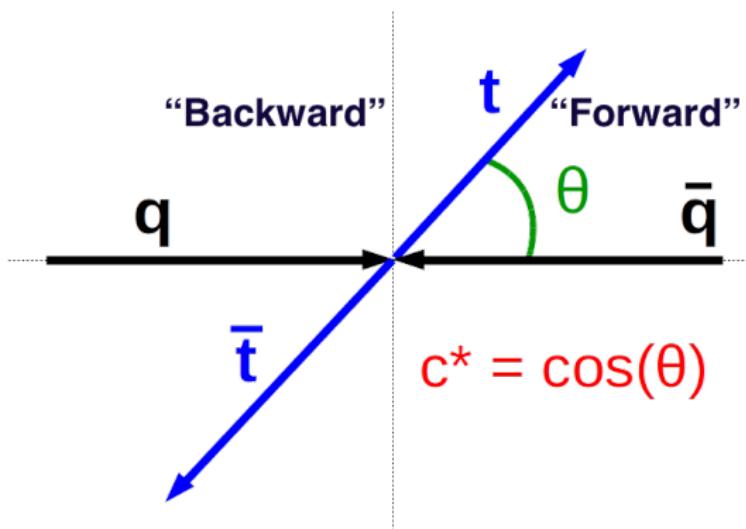

$$A_{FB} \equiv \frac{N_{forward} - N_{backward}}{N_{forward} + N_{backward}}$$

What is A_{FB} ?

- ▶ Consider $q\bar{q} \rightarrow t\bar{t}$
- ▶ top and antitop leave back to back
- ▶ c^* measures whether an event is “forward” or “backward”
- ▶ A_{FB} counts the numbers of forward/backward events and quantifies asymmetry
- ▶ **Predicted from SM:**
 $A_{FB} \approx 10\%$

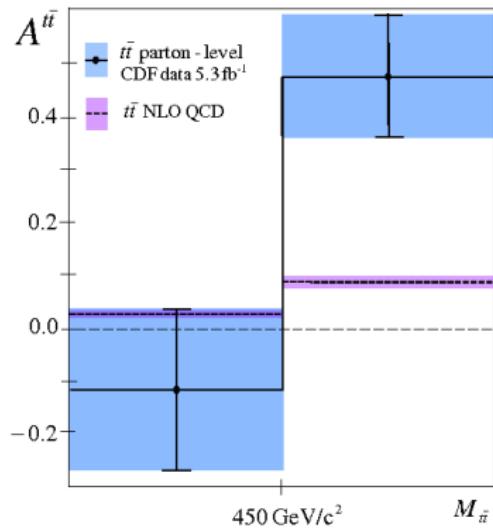

Center of Mass frame

$$A_{FB} \equiv \frac{N_{forward} - N_{backward}}{N_{forward} + N_{backward}}$$

A_{FB} Predictions and Measurements

- ▶ Collider Detector at Fermilab (CDF) Experiment measured A_{FB} in 2011
- ▶ Found anomalously large value, $A_{FB} \approx 45\%$
- ▶ Using 3.2 fb^{-1} of data, found 2.3σ deviation from expectation
- ▶ Measurement of A_{FB} never performed by any LHC Experiment

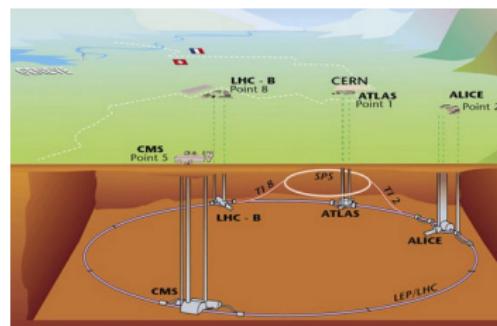

Plot: CDF Collaboration, *Evidence for a Mass Dependent Forward-Backward Asymmetry in Top Quark Pair Production*,
[arXiv:1101.0034 \[hep-ex\]](https://arxiv.org/abs/1101.0034)

The Large Hadron Collider (LHC) and the Compact Muon Solenoid (CMS) Detector

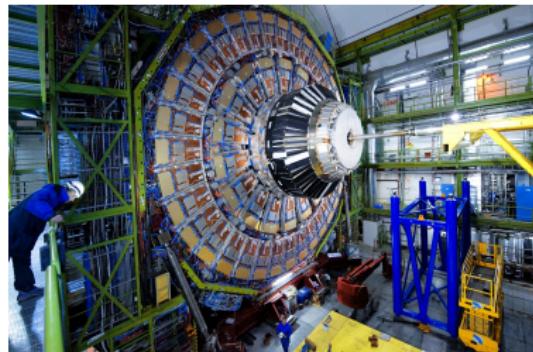

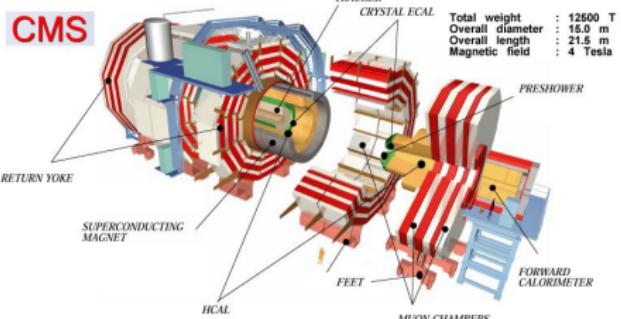

The Large Hadron Collider

- ▶ Largest and highest energy particle collider in the world
- ▶ Collides beams of protons
- ▶ 27km circumference, 175m underground
- ▶ Built at CERN just outside of Geneva
- ▶ Massive international collaboration
- ▶ 4 main detectors

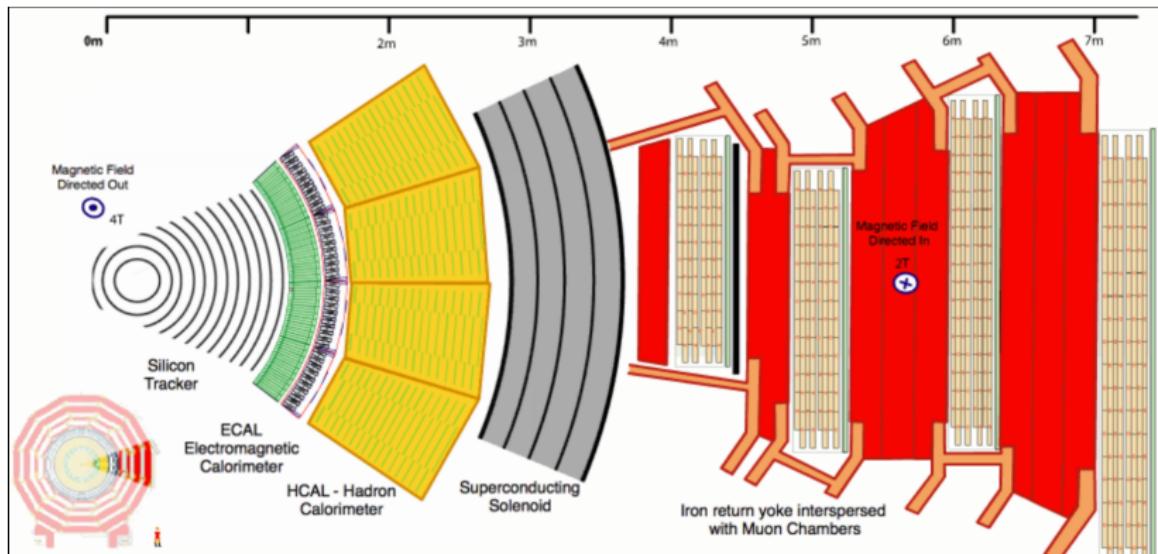

The CMS Experiment

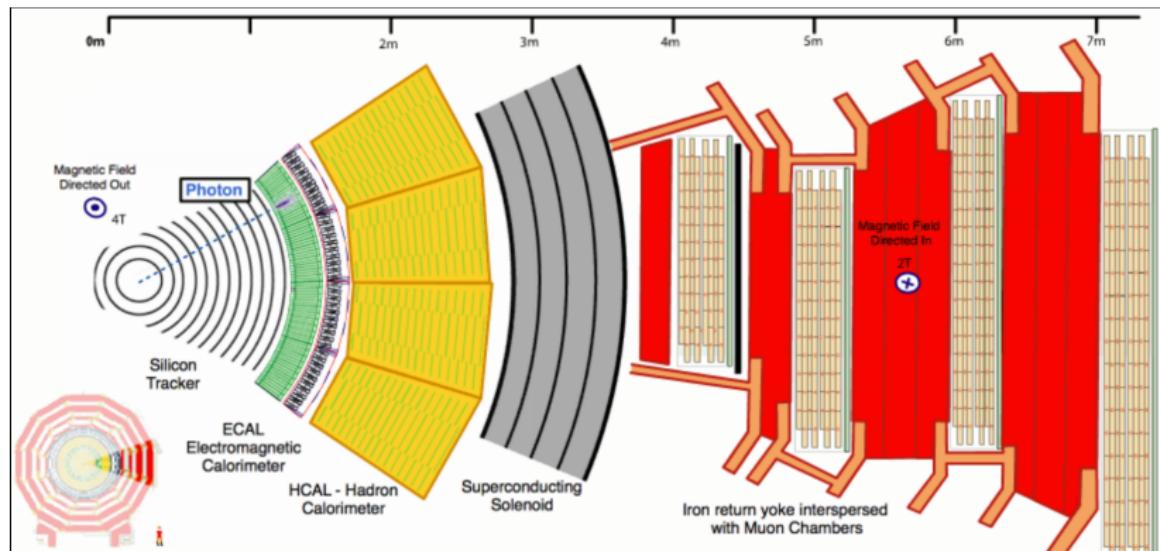

- ▶ General purpose detector
- ▶ Measures energies and paths of particles
- ▶ About 3,000 people, 40 countries

Particle Behavior in the CMS Detector

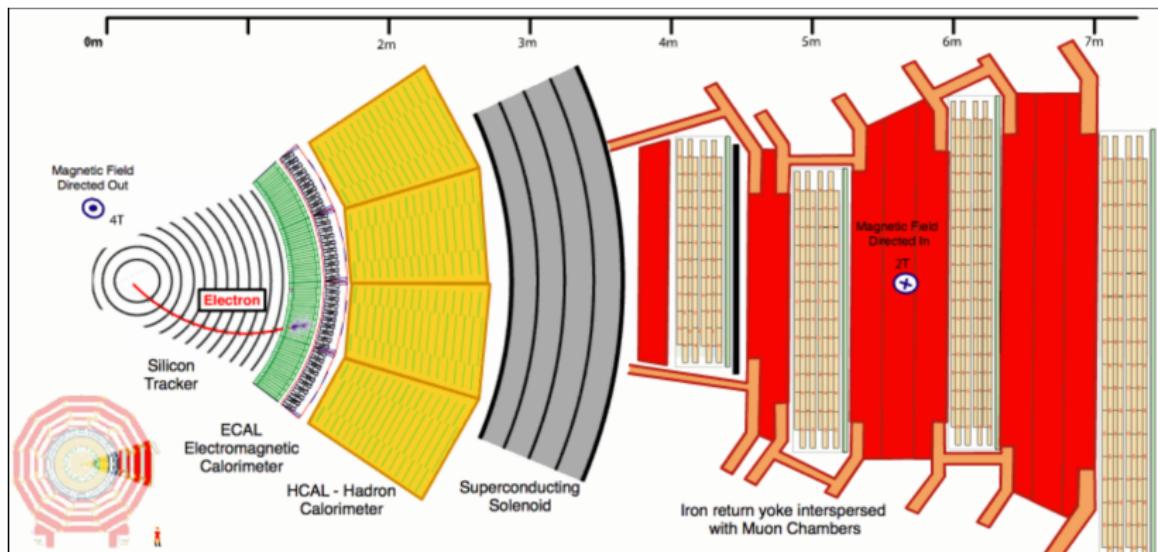

Particle Behavior in the CMS Detector

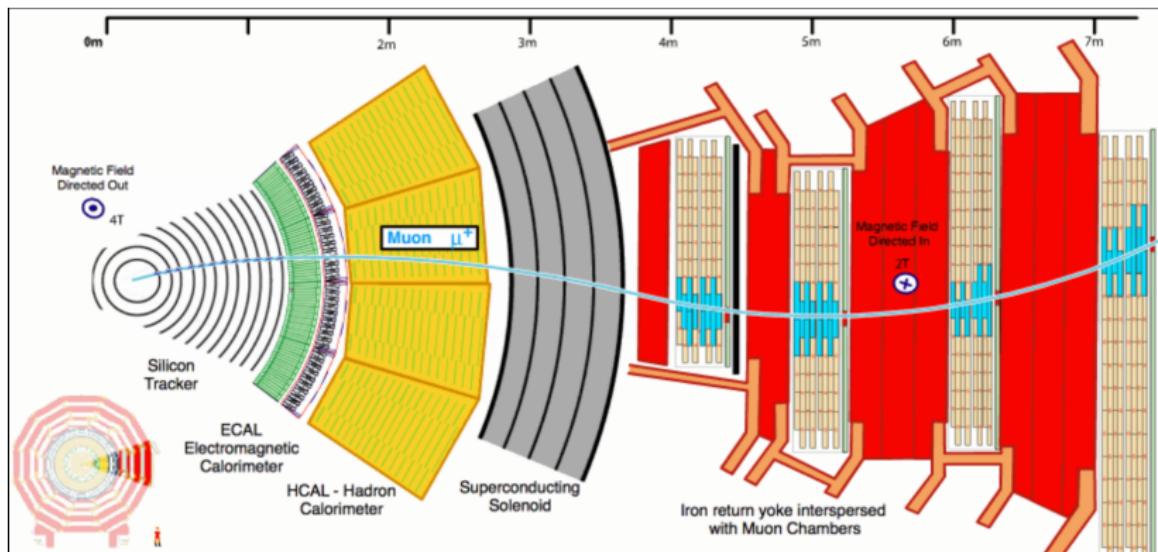

Photons leave energy deposits

Particle Behavior in the CMS Detector

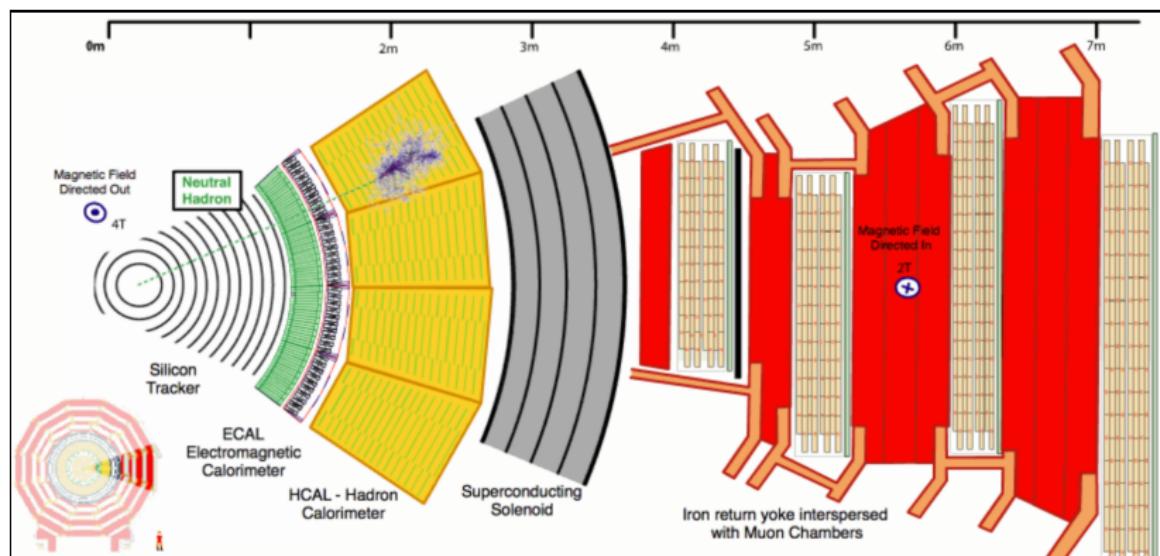

Leptons (Muons, Electrons) leave tracks and energy deposits

Particle Behavior in the CMS Detector

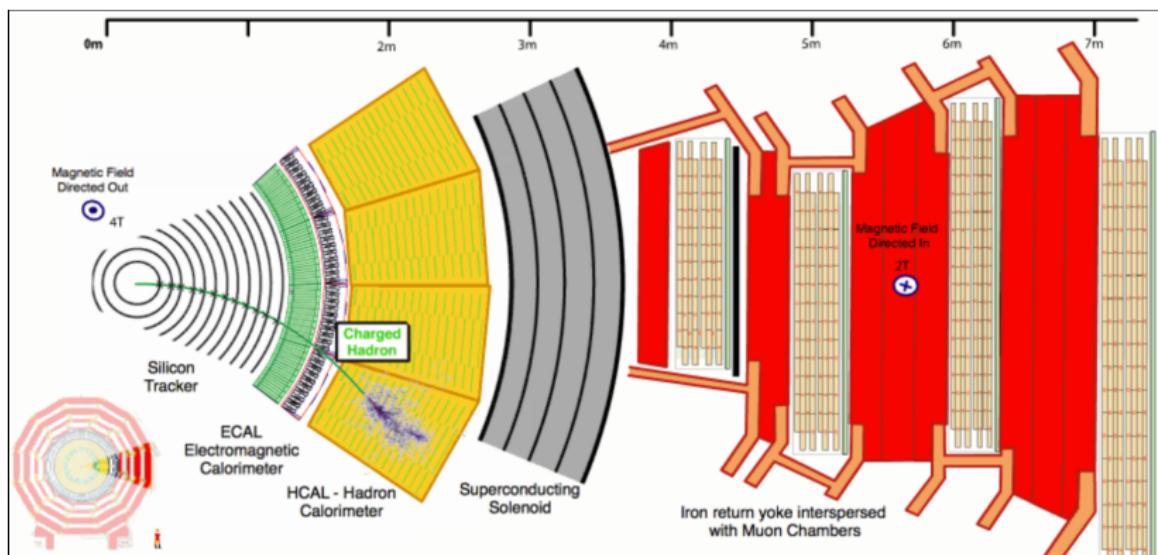

Leptons (Muons, Electrons) leave tracks and energy deposits

Particle Behavior in the CMS Detector

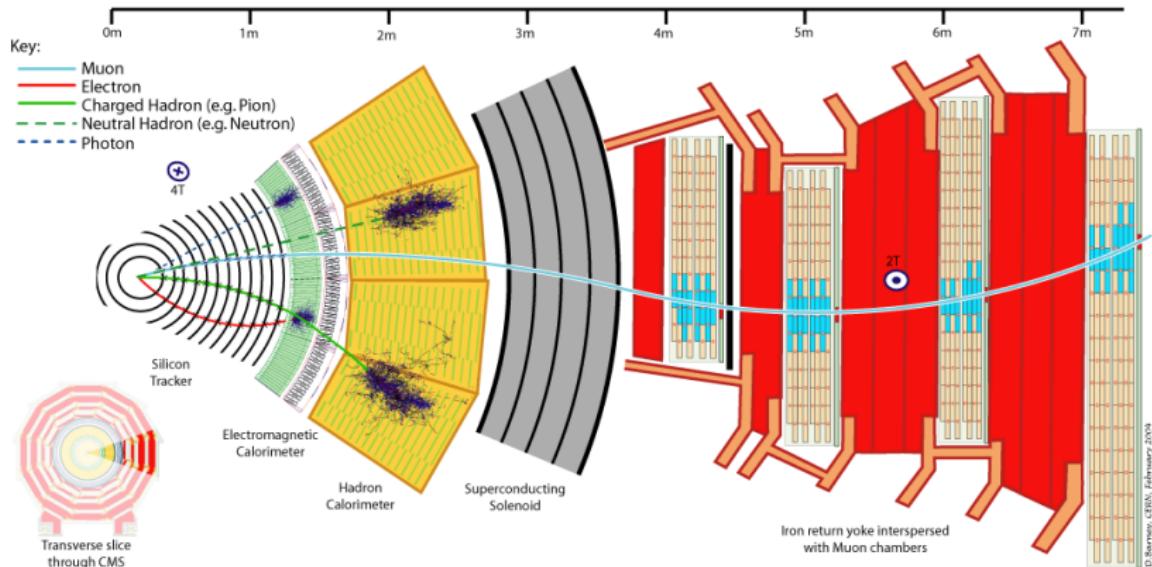

Hadrons (quark-containing particles) leave tracks and energy deposits
Decaying heavy quarks leave many tracks that we collect into “Jets”

Particle Behavior in the CMS Detector

Hadrons (quark-containing particles) leave tracks and energy deposits
Decaying heavy quarks leave many tracks that we collect into “Jets”

Particle Behavior in the CMS Detector

CMS measures all of the energy and momenta and anything left over (“Missing transverse energy” MET) is from an invisible neutrino

How we measure A_{FB}

What types of events will we see?

- ▶ quarks and gluons inside colliding protons combine energies to produce a wide variety of events.
- ▶ Signal: $q\bar{q} \rightarrow t\bar{t}$ events

What types of events will we see?

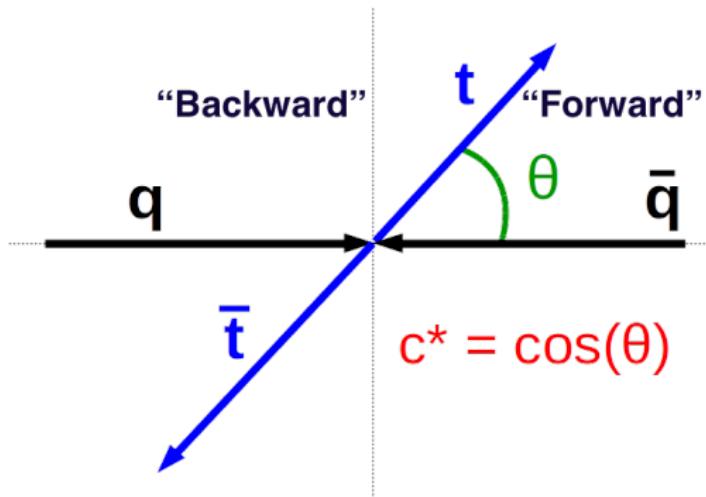

- ▶ quarks and gluons inside colliding protons combine energies to produce a wide variety of events.
- ▶ Signal: $q\bar{q} \rightarrow t\bar{t}$ events
- ▶ Backgrounds
 - ▶ $gg/qg \rightarrow t\bar{t}$ events
 - ▶ Similar (and much more abundant at the LHC), but A_{FB} is 0 or very small

What types of events will we see?

- ▶ quarks and gluons inside colliding protons combine energies to produce a wide variety of events.
- ▶ Signal: $q\bar{q} \rightarrow t\bar{t}$ events
- ▶ Backgrounds
 - ▶ $gg/qg \rightarrow t\bar{t}$ events
 - ▶ Similar (and much more abundant at the LHC), but A_{FB} is 0 or very small
 - ▶ “Single top” events
 - ▶ “Non-top multi-jet” (NTMJ) events
 - ▶ Distinguish top pairs using kinematics
 - ▶ Choose observables to distinguish $q\bar{q}/gg/qg \rightarrow t\bar{t}$

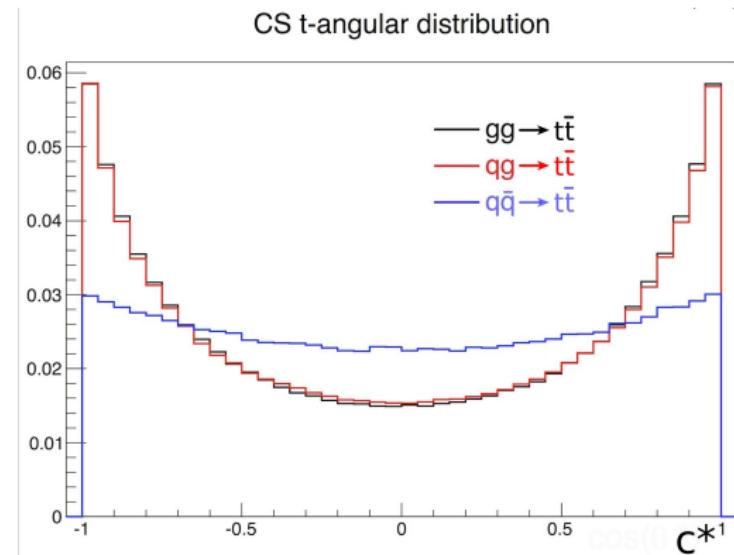

Physical Observables

- ▶ Production direction c^*
 - ▶ Main observable: shows asymmetry
 - ▶ Provides good discrimination
- ▶ Boost amount $|x_F|$
- ▶ Pairwise invariant mass M

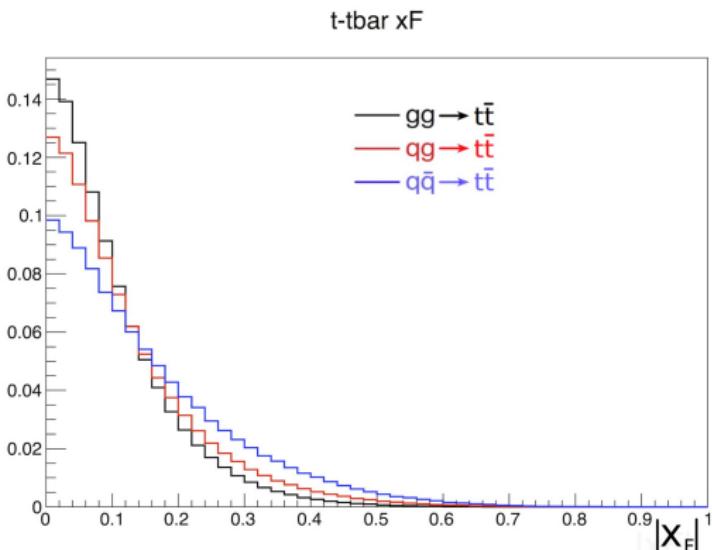

Physical Observables

- ▶ Production direction c^*
 - ▶ Main observable: shows asymmetry
 - ▶ Provides good discrimination
- ▶ Boost amount $|x_F|$
- ▶ Pairwise invariant mass M

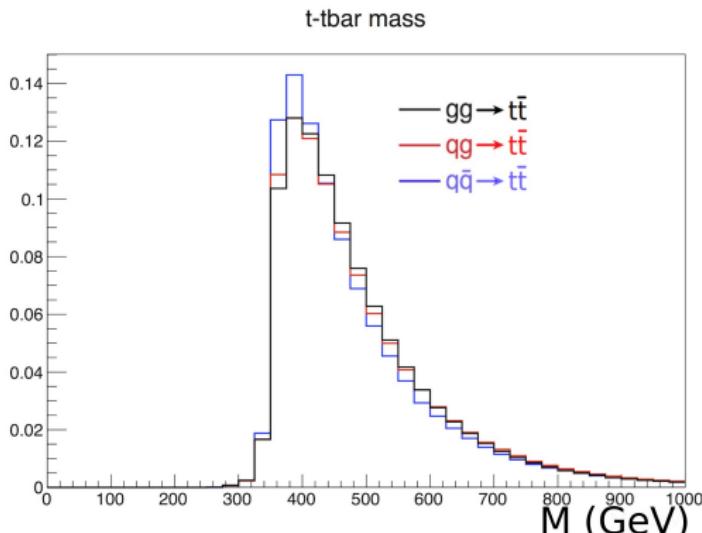

Physical Observables

- ▶ Production direction c^*
 - ▶ Main observable: shows asymmetry
 - ▶ Provides good discrimination
- ▶ Boost amount $|x_F|$
 - ▶ Proportional to momentum of $t\bar{t}$ pair
 - ▶ Also discriminates between production mechanisms
- ▶ Pairwise invariant mass M

Physical Observables

- ▶ Production direction c^*
 - ▶ Main observable: shows asymmetry
 - ▶ Provides good discrimination
- ▶ Boost amount $|x_F|$
 - ▶ Proportional to momentum of $t\bar{t}$ pair
 - ▶ Also discriminates between production mechanisms
- ▶ Pairwise invariant mass M
 - ▶ CDF result: A_{FB} is $M_{t\bar{t}}$ -dependent
 - ▶ Gives good separation for “boosted” events

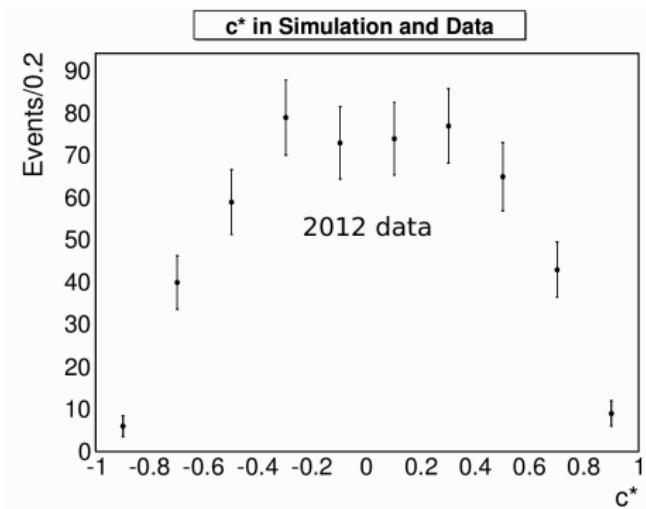

Differential Cross Section

If $\vec{x} \equiv (c^*, x_F, M)$:

$$\frac{d\sigma}{d\vec{x}}(\text{total}) \propto \frac{d\sigma}{d\vec{x}}(\text{background}) + \frac{d\sigma}{d\vec{x}}(gg; M^2) + \frac{d\sigma}{d\vec{x}}(q\bar{q}; M^2)$$

Describe how many events we expect with given c^*, x_F , and M

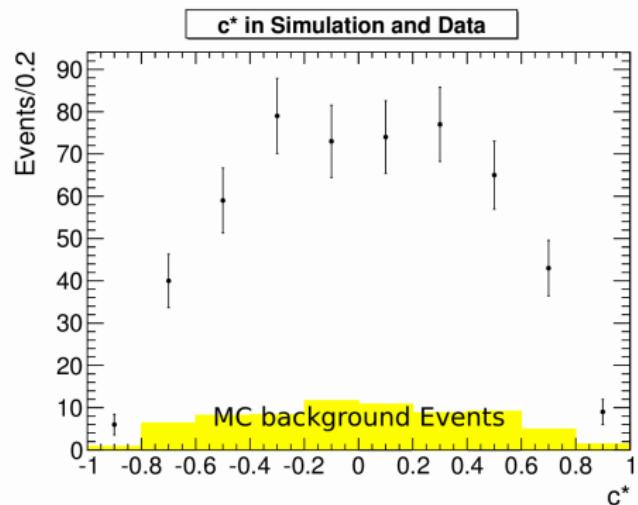

Differential Cross Section

If $\vec{x} \equiv (c^*, x_F, M)$:

$$\frac{d\sigma}{d\vec{x}}(\text{total}) \propto \frac{d\sigma}{d\vec{x}}(\text{background}) + \frac{d\sigma}{d\vec{x}}(gg; M^2) + \frac{d\sigma}{d\vec{x}}(q\bar{q}; M^2)$$

All Background Processes

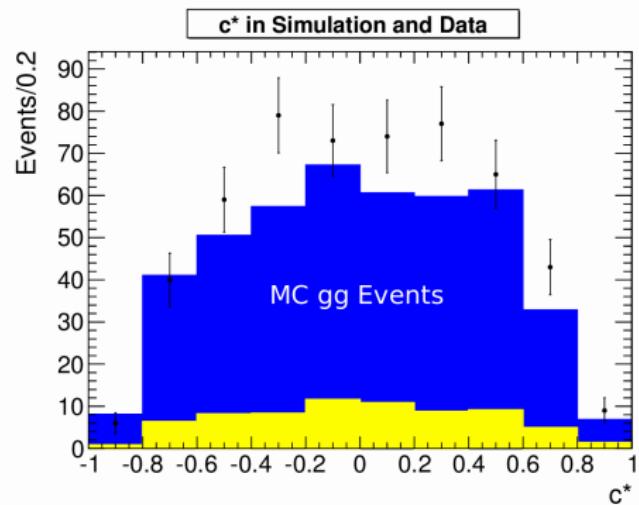

Differential Cross Section

If $\vec{x} \equiv (c^*, x_F, M)$:

$$\frac{d\sigma}{d\vec{x}}(\text{total}) \propto \frac{d\sigma}{d\vec{x}}(\text{background}) + \frac{d\sigma}{d\vec{x}}(gg; M^2) + \frac{d\sigma}{d\vec{x}}(q\bar{q}; M^2)$$

For each subprocess:

$$\frac{d\sigma}{d\vec{x}}(gg; M^2) \propto F_{gg}(M^2, \beta, c^{*2})$$

Differential Cross Section

If $\vec{x} \equiv (c^*, x_F, M)$:

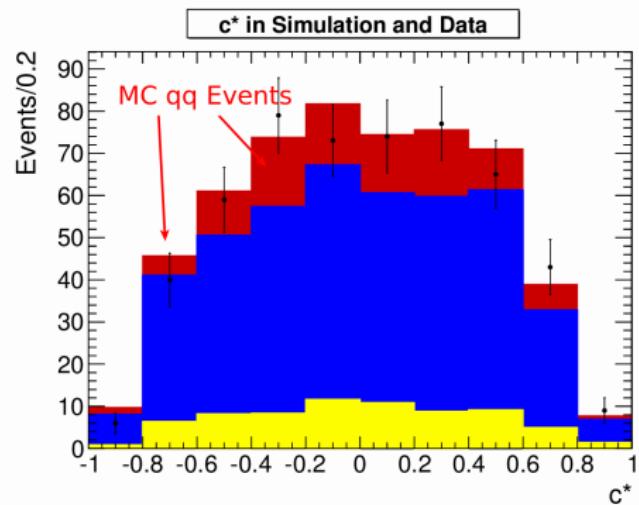

$$\frac{d\sigma}{d\vec{x}}(\text{total}) \propto \frac{d\sigma}{d\vec{x}}(\text{background}) + \frac{d\sigma}{d\vec{x}}(gg; M^2) + \frac{d\sigma}{d\vec{x}}(q\bar{q}; M^2)$$

For each subprocess:

$$\frac{d\sigma}{d\vec{x}}(gg; M^2) \propto F_{gg}(M^2, \beta, c^{*2})$$

$$\frac{d\sigma}{d\vec{x}}(q\bar{q}; M^2) \propto F_{q\bar{q}s}(M^2, \beta, c^{*2})$$

$$+ A_{FB} c^* F_{q\bar{q}a}(M^2, \beta)$$

Differential Cross Section

If $\vec{x} \equiv (c^*, x_F, M)$:

$$\frac{d\sigma}{d\vec{x}}(\text{total}) \propto \frac{d\sigma}{d\vec{x}}(\text{background}) + \frac{d\sigma}{d\vec{x}}(gg; M^2) + \frac{d\sigma}{d\vec{x}}(q\bar{q}; M^2)$$

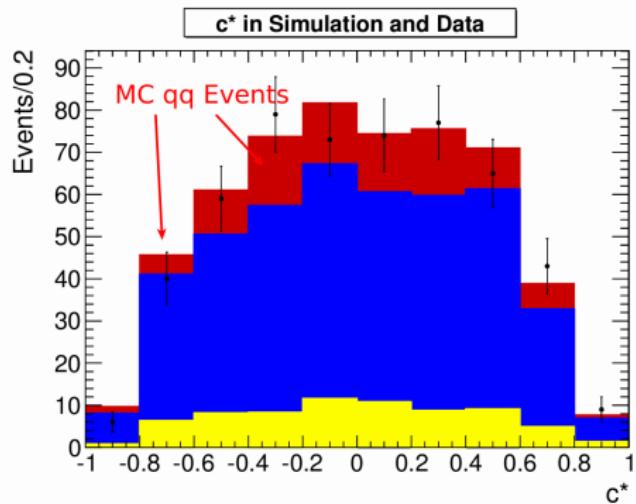

For each subprocess:

$$\frac{d\sigma}{d\vec{x}}(gg; M^2) \propto F_{gg}(M^2, \beta, c^{*2})$$

$$\frac{d\sigma}{d\vec{x}}(q\bar{q}; M^2) \propto F_{q\bar{q}s}(M^2, \beta, c^{*2})$$

$$+ A_{FB} c^* F_{q\bar{q}a}(M^2, \beta)$$

A_{FB} : Linear Asymmetry

Fitting Plan

1. Simulate $q\bar{q} \rightarrow t\bar{t}$, $gg/qg \rightarrow t\bar{t}$, and background processes
2. Select and Reconstruct Monte Carlo and data events in the same way
3. Build 3D template (histogram in observables) from Monte Carlo for each term in cross section
 - ▶ Symmetrize/Antisymmetrize $q\bar{q} \rightarrow t\bar{t}$ to make $F_{q\bar{q}s}/F_{q\bar{q}a}$
4. Sum all the templates and allow their relative amounts to float in a fit to data
5. Extract A_{FB}

Measuring the $t\bar{t}$ Forward-Backward Asymmetry at the LHC

N. Eminizer, L. Feng, M. Swartz

Abstract

This note discusses a scheme to extract the top quark forward-backward asymmetry from LHC data. The technique is based upon a linear extension of the tree-level cross section for quark-antiquark initial states and it sensitively isolates those initial states from gluon-gluon and quark-gluon initial states. The statistical power of the technique exceeds that of the charge asymmetry technique that has been in use to study LHC data. The quantity produced by this technique is already corrected to parton level and is directly comparable to similar quantities derived from the Tevatron measurements.

In the longer term, this technique could be used to search for interference effects from $t\bar{t}$ resonances at larger pair masses using partly merged semileptonic events. Because large interference effects can occur at pair masses well below or above the actual resonance mass and are insensitive to the resonance width, this technique would be quite complementary to techniques that search for “bumps” in the $t\bar{t}$ mass spectrum.

What's Next

Next Steps

- ▶ A few refinements
- ▶ “Start over” with 13TeV data
 - ▶ Higher cross section ($\sigma_{incl}^{t\bar{t}} = 248 pb \rightarrow 816 pb$)
 - ▶ Greater Luminosity
 - ▶ Increased boosted event abundance
- ▶ Extension to anomalous chromoelectric/chromomagnetic moments
- ▶ Adapt as high-mass $t\bar{t}$ resonance search

Why is $A_{FB} \neq 0$ in the Standard Model?

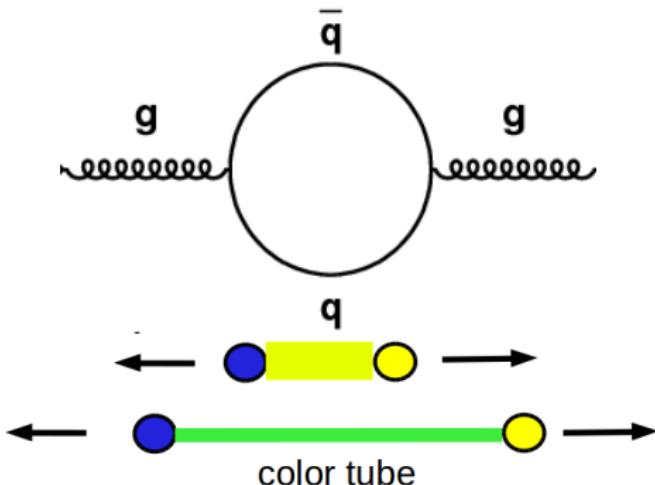

New physics with A_{FB}

Chiral couplings can create large A_{FB} effects even far from resonances

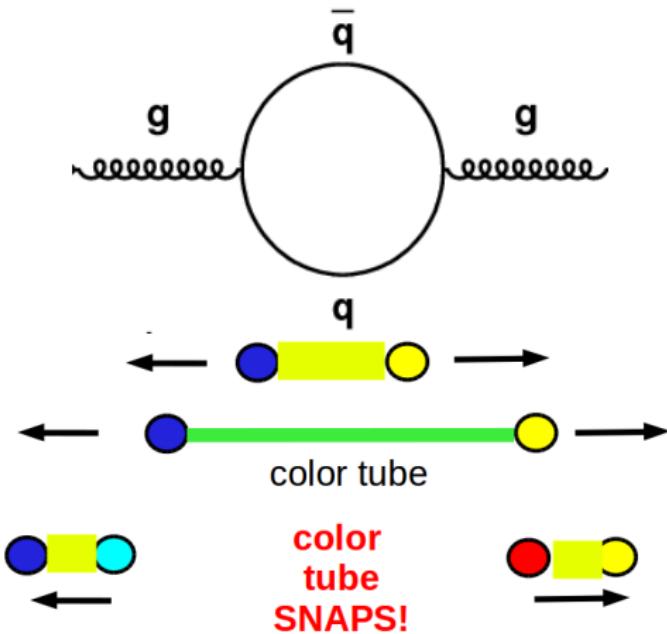

What is a jet?

- ▶ Strong force is weaker at larger separation and energy ("asymptotic freedom")
- ▶ Begin pulling a meson apart
- ▶ "Antiscreening" leads to a "color tube"

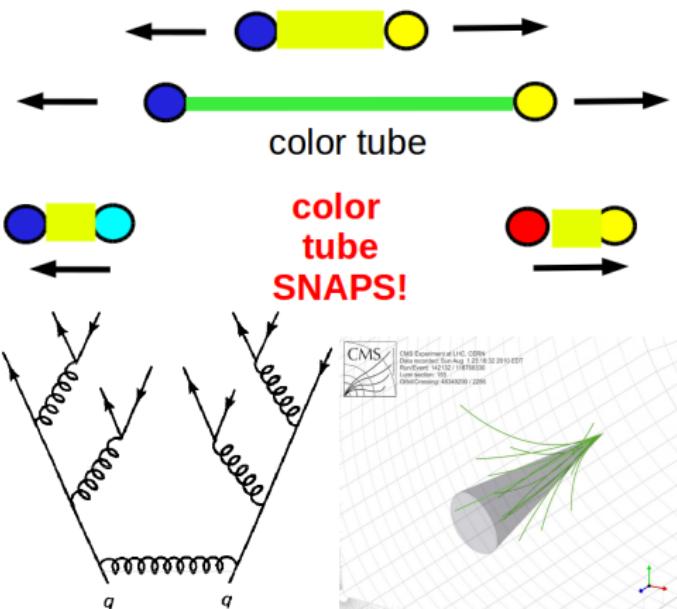

What is a jet?

- ▶ Strong force is weaker at larger separation and energy (“asymptotic freedom”)
- ▶ Begin pulling a meson apart
- ▶ “Antiscreening” leads to a “color tube”
- ▶ Stored energy increases until color tube snaps
- ▶ The virtual pair becomes real and there are now two mesons

What is a jet?

- ▶ Strong force is weaker at larger separation and energy (“asymptotic freedom”)
- ▶ Begin pulling a meson apart
- ▶ “Antiscreening” leads to a “color tube”
- ▶ Stored energy increases until color tube snaps
- ▶ The virtual pair becomes real and there are now two mesons
- ▶ A decaying quark becomes a shower of hadrons, or “jet”

The Standard Model: Interactions

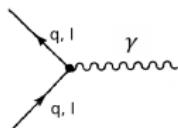

- ▶ “Bosons” mediate interactions

The Eightfold Way

- ▶ Proposed by Gell-Mann in 1960s before quark theory
- ▶ Organizes lightest mesons/baryons into representations of $SU(3)$
- ▶ Approximate strong interaction flavor symmetry for u , d , s
- ▶ Can be extended to flavor $SU(6)$

Isospin Analysis of Scattering

In the three-quark model, lightest mesons and baryons can be assigned a vector quantity called “Isospin” (I) with a projection value I_3 in analogy to spin, i.e. :

$$\begin{aligned}\pi^+ &= |I = 1 \quad I_3 = 1\rangle, & \pi^0 &= |1 \quad 0\rangle, & \pi^- &= |1 \quad -1\rangle \\ p &= |1/2 \quad 1/2\rangle, & n &= |1/2 \quad -1/2\rangle\end{aligned}$$

Strong interactions conserve isospin, so scattering amplitude relations can be calculated by decomposing scattering processes into isospin components :

$$\begin{aligned}\pi^+ + n &\rightarrow \pi^+ + n = (\langle 1/2 \quad -1/2 | \langle 1 \quad 1 |) (| 1/2 \quad -1/2 \rangle | 1 \quad 1 \rangle) \\ &= \frac{1}{3} \langle ^3/2 \quad 1/2 | ^3/2 \quad 1/2 \rangle + \frac{2}{3} \langle ^1/2 \quad 1/2 | ^1/2 \quad 1/2 \rangle = \frac{1}{3} \mathcal{M}_3 + \frac{2}{3} \mathcal{M}_1 \\ \pi^+ + n &\rightarrow \pi^0 + p = (\langle 1/2 \quad 1/2 | \langle 1 \quad 0 |) (| 1/2 \quad -1/2 \rangle | 1 \quad 1 \rangle) \\ &= \frac{\sqrt{2}}{3} \langle ^3/2 \quad 1/2 | ^3/2 \quad 1/2 \rangle - \frac{\sqrt{2}}{3} \langle ^1/2 \quad 1/2 | ^1/2 \quad 1/2 \rangle = \frac{\sqrt{2}}{3} \mathcal{M}_3 + \frac{\sqrt{2}}{3} \mathcal{M}_1 \\ \frac{\sigma(\pi^+ + n \rightarrow \pi^+ + n)}{\sigma(\pi^+ + n \rightarrow \pi^0 + p)} &= \frac{|\mathcal{M}_3 + 2\mathcal{M}_1|^2}{2|\mathcal{M}_3 + \mathcal{M}_1|^2} \approx \frac{1}{2}\end{aligned}$$

The Feynman Rules (External Lines, Propagators, and QED vertex factors)

External Lines

Spin 0:	(nothing)
Spin $\frac{1}{2}$:	$\begin{cases} \text{Incoming particle: } u \\ \text{Incoming antiparticle: } \bar{v} \\ \text{Outgoing particle: } \bar{u} \\ \text{Outgoing antiparticle: } v \end{cases}$
Spin 1:	$\begin{cases} \text{incoming: } \epsilon^\mu \\ \text{outgoing: } \epsilon^\mu{}^* \end{cases}$

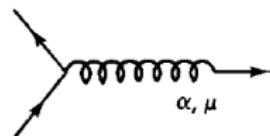

Propagators

Spin 0:	$\frac{i}{q^2 - (mc)^2}$
Spin $\frac{1}{2}$:	$\frac{i(q + mc)}{q^2 - (mc)^2}$
Spin 1:	$\begin{cases} \text{Massless: } \frac{-ig_{\mu\nu}}{q^2} \\ \text{Massive: } \frac{-i[g_{\mu\nu} - q_\mu q_\nu / (mc)^2]}{q^2 - (mc)^2} \end{cases}$

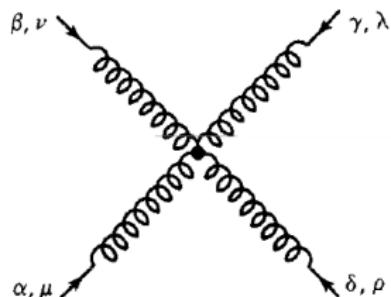

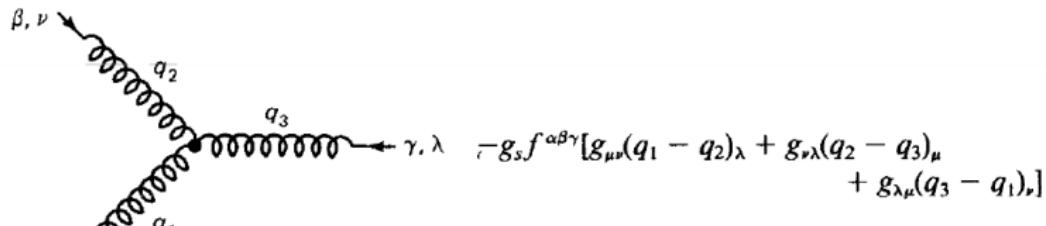

The Feynman Rules (QCD vertex factors)

QCD:

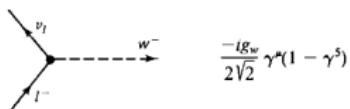

$$\frac{-ig_s}{2} \lambda^\alpha \gamma^\mu$$

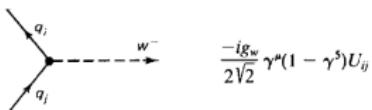

$$\begin{aligned} & -ig_s^2 [f^{\alpha\beta\eta} f^{\gamma\delta\eta} (g_{\mu\lambda} g_{\nu\rho} - g_{\mu\rho} g_{\nu\lambda}) \\ & + f^{\alpha\delta\eta} f^{\beta\gamma\eta} (g_{\mu\nu} g_{\lambda\rho} - g_{\mu\lambda} g_{\nu\rho}) \\ & + f^{\alpha\gamma\eta} f^{\delta\beta\eta} (g_{\mu\rho} g_{\nu\lambda} - g_{\mu\nu} g_{\lambda\rho})] \end{aligned}$$

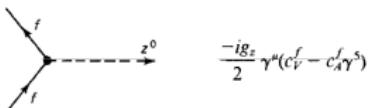

The Feynman Rules (Electroweak vertex factors)

(Here l is any lepton, and ν_l the corresponding neutrino.)

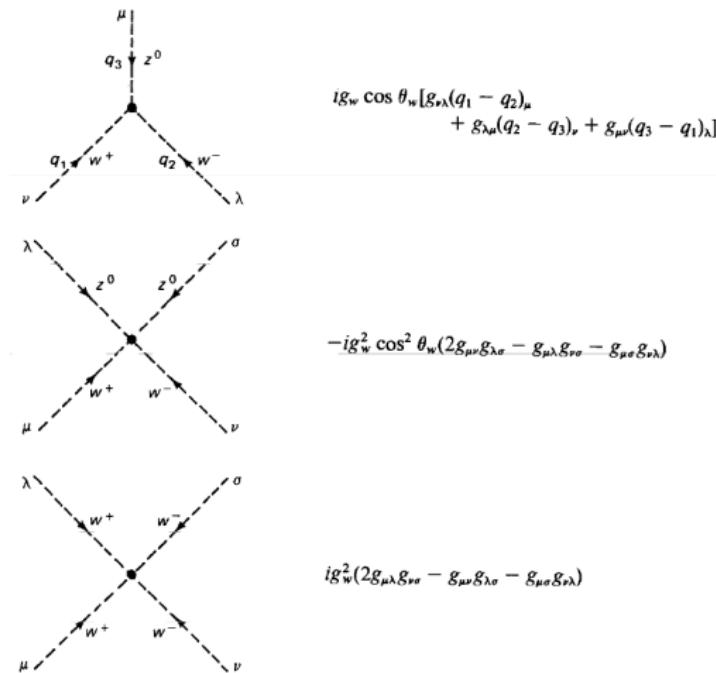

(Here $i = u, c$, or t , and $j = d, s$, or b ;
 U is the Kobayashi-Maskawa matrix.)

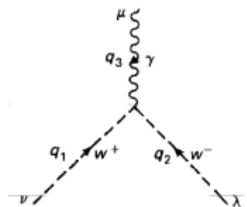

(Here f is any quark or lepton.)

f	c_V	c_A
ν_e, ν_μ, ν_τ	$\frac{1}{2}$	$\frac{1}{2}$
e^-, μ^-, τ^-	$-\frac{1}{2} + 2 \sin^2 \theta_w$	$-\frac{1}{2}$
u, c, t	$\frac{1}{2} - \frac{4}{3} \sin^2 \theta_w$	$\frac{1}{2}$
d, s, b	$-\frac{1}{2} + \frac{2}{3} \sin^2 \theta_w$	$-\frac{1}{2}$

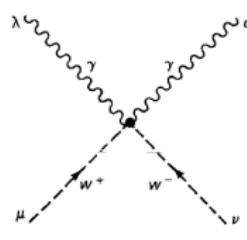

The Feynman Rules (Electroweak vertex factors)

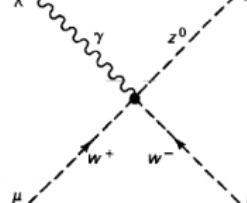

The Feynman Rules (Electroweak vertex factors)

$$ig_e g_{\nu\lambda} (q_1 - q_2)_\mu + g_{\lambda\mu} (q_2 - q_3)_\nu + g_{\mu\nu} (q_3 - q_1)_\lambda]$$

$$-ig_e^2 (2g_{\mu\nu}g_{\lambda\sigma} - g_{\mu\lambda}g_{\nu\sigma} - g_{\mu\sigma}g_{\nu\lambda})$$

$$-ig_e g_w \cos \theta_w (2g_{\mu\nu}g_{\lambda\sigma} - g_{\mu\lambda}g_{\nu\sigma} - g_{\mu\sigma}g_{\nu\lambda})$$

Conserved Quantities

When writing down particle interactions and Feynman Diagrams, check conservation of:

1. Electric charge (some may be carried away by a W^\pm)
2. Color charge (only applicable to strong interactions, gluons are dual-colored)
3. Baryon number
4. Lepton number (only applicable to EM/weak)
5. Lepton flavor (except for neutrino oscillations)
6. Quark flavor (only applicable to EM/strong)

Weak Interaction Selection Rules

1. Conservation of Lepton Flavor Number L_e, L_μ, L_τ
 - ▶ In absence of neutrino oscillations
2. Strangeness changing interactions ($\Delta S \neq 0$) are suppressed by a factor of ≈ 10
 - ▶ $\Delta S = 2$ interactions are extremely suppressed
3. For hadrons in $\Delta S \neq 0$ interactions, $\Delta S = \Delta Q$
 - ▶ i.e. $K^+ \rightarrow \pi^0 \mu^+ \nu_\mu$ but not $K^+ \rightarrow \pi^+ \pi^+ e^- \bar{\nu}_e$
4. No $\Delta S = 1$ neutral currents at tree level
 - ▶ “GIM Mechanism”
5. Same rules apply for changes in any heavy flavor number ($\Delta S, \Delta C, \Delta B$)

Fermi's Golden Rule

Transition rate from one state to another is the magnitude (amplitude squared) multiplied by the available phase space

Decays ($1 \rightarrow 2 + 3 + \dots + n$)

$$\Gamma = \frac{S}{2m_1} \int |\mathcal{M}|^2 (2\pi)^4 \delta^4(p_1 - \dots - p_n)$$

$$\times \prod_{j=2}^n 2\pi \delta(p_j^2 - m_j^2) \theta(p_j^0) \frac{d^4 p_j}{(2\pi)^4}$$

Scattering ($1 + 2 \rightarrow 3 + 4 + \dots + n$)

$$\sigma = \frac{S}{4\sqrt{(p_1 \cdot p_2)^2 - (m_1 m_2)^2}} \int |\mathcal{M}|^2 (2\pi)^4 \delta^4(p_1 \pm \dots - p_n)$$

$$\times \prod_{j=3}^n 2\pi \delta(p_j^2 - m_j^2) \theta(p_j^0) \frac{d^4 p_j}{(2\pi)^4}$$

Two-body ($1 \rightarrow 2 + 3$)

$$\Gamma = \frac{S|\mathbf{p}|}{8\pi m_1^2} |\mathcal{M}|^2$$

Two-body, CM frame ($1 + 2 \rightarrow 3 + 4$)

$$\frac{d\sigma}{d\Omega} = \left(\frac{1}{8\pi}\right)^2 \frac{S}{(E_1 + E_2)^2} \frac{|\mathbf{p}_f|}{|\mathbf{p}_i|} |\mathcal{M}|^2$$

Generalized Free Particle Lagrangians and Equations of Motion

Spin 0 (scalar) field ϕ ("Klein-Gordon")

$$\mathcal{L} = \frac{1}{2}\partial_\mu\phi\partial^\mu\phi - \frac{1}{2}m^2\phi^2 \quad (-\partial_\mu\partial^\mu + m^2)\phi = 0$$

Spin 1/2 (spinor) field ψ ("Dirac")

$$\mathcal{L} = i\bar{\psi}\not{\partial}\psi - m^2\bar{\psi}\psi \quad (i\not{\partial} - m)\psi = 0$$

Spin 1 (vector) field A^μ ("Proca")

$$\mathcal{L} = \frac{-1}{16\pi}F^{\mu\nu}F_{\mu\nu} + \frac{1}{8\pi}m^2A^\nu A_\nu \quad \partial_\mu F^{\mu\nu} + m^2A^\nu = 0$$

where $F^{\mu\nu} \equiv \partial^\mu A^\nu - \partial^\nu A^\mu$

Gamma Matrices

$$\gamma^0 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \quad \gamma^1 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}$$

$$\gamma^2 = \begin{pmatrix} 0 & 0 & 0 & -i \\ 0 & 0 & i & 0 \\ 0 & i & 0 & 0 \\ -i & 0 & 0 & 0 \end{pmatrix}, \quad \gamma^3 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}.$$

Gamma Matrices

Num	Identity
1	$\gamma^\mu \gamma_\mu = 4I_4$
2	$\gamma^\mu \gamma^\nu \gamma_\mu = -2\gamma^\nu$
3	$\gamma^\mu \gamma^\nu \gamma^\rho \gamma_\mu = 4\eta^{\nu\rho} I_4$
4	$\gamma^\mu \gamma^\nu \gamma^\rho \gamma^\sigma \gamma_\mu = -2\gamma^\sigma \gamma^\rho \gamma^\nu$
5	$\gamma^\mu \gamma^\nu \gamma^\rho = \eta^{\mu\nu} \gamma^\rho + \eta^{\nu\rho} \gamma^\mu - \eta^{\mu\rho} \gamma^\nu - i\epsilon^{\sigma\mu\nu\rho} \gamma_\sigma \gamma^5$

Gamma Matrices

Num	Identity
0	$\text{tr}(\gamma^\mu) = 0$
1	trace of any product of an odd number of γ^μ is zero
2	trace of γ^5 times a product of an odd number of γ^μ is still zero
3	$\text{tr}(\gamma^\mu \gamma^\nu) = 4\eta^{\mu\nu}$
4	$\text{tr}(\gamma^\mu \gamma^\nu \gamma^\rho \gamma^\sigma) = 4(\eta^{\mu\nu}\eta^{\rho\sigma} - \eta^{\mu\rho}\eta^{\nu\sigma} + \eta^{\mu\sigma}\eta^{\nu\rho})$
5	$\text{tr}(\gamma^5) = \text{tr}(\gamma^\mu \gamma^\nu \gamma^5) = 0$
6	$\text{tr}(\gamma^\mu \gamma^\nu \gamma^\rho \gamma^\sigma \gamma^5) = 4i\epsilon^{\mu\nu\rho\sigma}$
7	$\text{tr}(\gamma^{\mu_1} \dots \gamma^{\mu_n}) = \text{tr}(\gamma^{\mu_n} \dots \gamma^{\mu_1})$

Gamma Matrices

Weyl (chiral) basis [\[edit\]](#)

Another common choice is the *Weyl* or *chiral basis*, in which γ^k remains the same but γ^0 is different, and so γ^5 is also different, and diagonal,

$$\gamma^0 = \begin{pmatrix} 0 & I_2 \\ I_2 & 0 \end{pmatrix}, \quad \gamma^k = \begin{pmatrix} 0 & \sigma^k \\ -\sigma^k & 0 \end{pmatrix}, \quad \gamma^5 = \begin{pmatrix} -I_2 & 0 \\ 0 & I_2 \end{pmatrix},$$

or in more compact notation:

$$\gamma^\mu = \begin{pmatrix} 0 & \sigma^\mu \\ \bar{\sigma}^\mu & 0 \end{pmatrix}, \quad \sigma^\mu \equiv (1, \sigma^i), \quad \bar{\sigma}^\mu \equiv (1, -\sigma^i).$$

The *Weyl* basis has the advantage that its *chiral projections* take a simple form,

$$\psi_L = \frac{1}{2}(1 - \gamma^5)\psi = \begin{pmatrix} I_2 & 0 \\ 0 & 0 \end{pmatrix}\psi, \quad \psi_R = \frac{1}{2}(1 + \gamma^5)\psi = \begin{pmatrix} 0 & 0 \\ 0 & I_2 \end{pmatrix}\psi.$$

The idempotence of the chiral projections is manifest. By slightly abusing the notation and reusing the symbols $\psi_{L/R}$ we can then identify

$$\psi = \begin{pmatrix} \psi_L \\ \psi_R \end{pmatrix},$$

Gell-Mann Matrices

An important representation involves 3×3 matrices, because the group elements then act on complex vectors with 3 entries, i.e., on the [fundamental representation](#) of the group. A particular choice of this representation is

$$\lambda_1 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \lambda_2 = \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \lambda_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

$$\lambda_4 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix} \quad \lambda_5 = \begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix}$$

$$\lambda_6 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} \quad \lambda_7 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix} \quad \lambda_8 = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}$$

and $g_i = \lambda_i/2$.

These matrices are [traceless](#), Hermitian, and obey the extra relation $\text{tr}(\lambda_i \lambda_j) = 2\delta_{ij}$. These properties were chosen by Gell-Mann because they then generalize the [Pauli matrices](#) for [SU\(2\)](#). They also naturally extend to general [SU\(n\)](#), cf. [Generalizations of Pauli matrices](#).

Electromagnetism and $U(1)$

- ▶ Begin with Dirac Lagrangian for a spin-1/2 field
- ▶ Assert global phase symmetry also holds locally
- ▶ Must change derivative to “covariant derivative”
- ▶ Introduces a massless vector field

$$\mathcal{L} = i\bar{\psi}\not{\partial}\psi - m\bar{\psi}\psi$$

$$\psi \rightarrow e^{i\theta}\psi \text{ becomes } \psi \rightarrow e^{i\theta(x)}\psi$$

$$\partial_\mu \rightarrow \mathcal{D}_\mu \equiv \partial_\mu + iqA_\mu$$

$$\mathcal{L}_{\text{QED}} = \bar{\psi}(i\not{\partial} - m)\psi - \frac{1}{4}F_{\mu\nu}F^{\mu\nu}$$

The electromagnetic interaction and the photon are the result of demanding Abelian $U(1)$ Gauge invariance of the Dirac Lagrangian

The Strong Interaction and flavor $SU(3)$

- ▶ Begin with Dirac Lagrangian for three spin-1/2 fields with three possible colors
- ▶ Invariant under unitary transformations $U(3)$
- ▶ Write generators in terms of a $U(1)$ phase and $SU(3)$ Gell-Mann matrices λ_α
- ▶ Demand locality of $SU(3)$ symmetry
- ▶ New covariant derivative
- ▶ Introduces a photon and eight gluons (one for each $SU(3)$ generator)

$$\mathcal{L} = i\bar{\psi}\not{\partial}\psi - m\bar{\psi}\psi \text{ where } \psi = \begin{pmatrix} \psi_r \\ \psi_g \\ \psi_b \end{pmatrix}$$

$$\psi \rightarrow U\psi \text{ with } U = e^{i\theta} e^{i\boldsymbol{\lambda} \cdot \mathbf{a}}$$

$$\psi \rightarrow e^{i\theta(x)} e^{-iq\boldsymbol{\lambda} \cdot \phi(x)} \psi$$

$$\partial_\mu \rightarrow \mathcal{D}_\mu \equiv \partial_\mu + iq\boldsymbol{\lambda} \cdot \mathbf{A}_\mu$$

$$\mathcal{L}_{QCD} = \bar{\psi}(i\not{\partial} - m)\psi - \frac{1}{16\pi} F_{\mu\nu}F^{\mu\nu}$$

Flavor Changing Interactions

W bosons couple between three “Weak Interaction Generations”

$$\begin{pmatrix} u \\ d' \\ s' \\ b' \end{pmatrix}, \begin{pmatrix} c \\ s' \\ b' \end{pmatrix}, \begin{pmatrix} t \\ b' \end{pmatrix}$$

Where the weak eigenstates are related to the mass eigenstates by three Euler angles $\theta_{12}, \theta_{23}, \theta_{13}$ and a CP-violating phase δ (here $c/s_{12} \equiv \cos \theta_{12} / \sin \theta_{12}$, etc.):

$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13} \end{pmatrix} \begin{pmatrix} d \\ s \\ b \end{pmatrix} = V \begin{pmatrix} d \\ s \\ b \end{pmatrix}$$

The magnitudes of the “CKM” matrix elements are (experimentally) :

$$|V_{ij}| = \begin{pmatrix} 0.97427 & 0.22534 & 0.00351 \\ 0.22520 & 0.97344 & 0.04120 \\ 0.00867 & 0.04040 & 0.99915 \end{pmatrix}$$

The Wolfenstein Parametrization

The CKM Matrix can be approximated as

$$V \approx \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix}$$

Where the new parameters are :

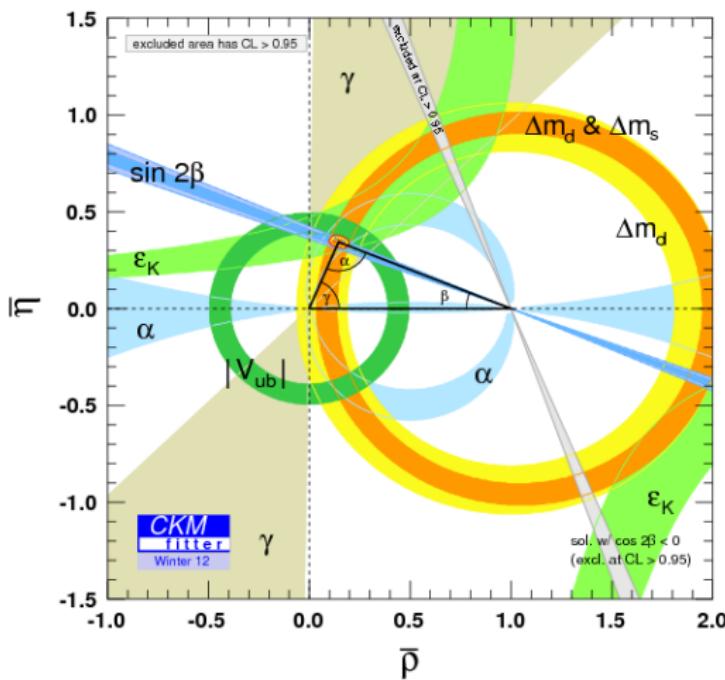

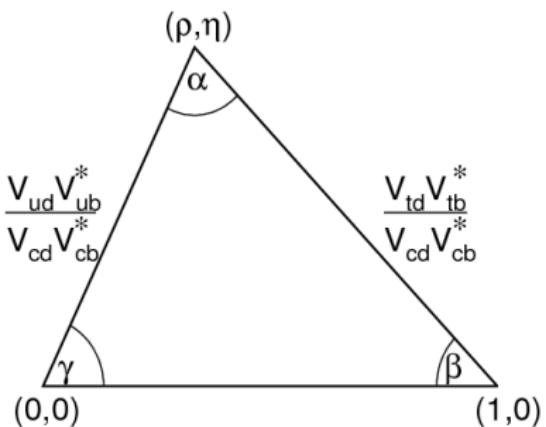

$$\lambda \equiv \sin \theta_{12}, A\lambda^2 \equiv \sin \theta_{23}, \text{ and } A\lambda^3(\rho - i\eta) \equiv \sin \theta_{13} e^{-i\delta}$$

Or, experimentally:

$$\lambda = 0.2257, A = 0.814, \rho = 0.135, \text{ and } \eta = 0.349$$

The Unitarity Triangle

The CKM matrix must be unitary in the Standard Model

Electroweak Unification

- ▶ Project out “left-handed” components of fermion spinors
- ▶ i.e. for $\ell \rightarrow \nu_\ell + W^\pm$, vertex factor is entirely “left-handed”
- ▶ Construct $SU(2)_L \otimes U(1)$ symmetry group with weak isospin/hypercharge by considering oppositely charged weak current
- ▶ Weak isospin couples to a triplet of vector bosons, \mathbf{W} , and weak hypercharge (including EM) couples to an isosinglet vector boson B

$$u_L \equiv \frac{(1-\gamma^5)}{2} u, \quad v_L \equiv \frac{(1+\gamma^5)}{2} v$$

$$\bar{\nu}_{\nu_\ell, L} \gamma_\mu u_{\ell, L}$$

$$\mathbf{j}_\mu = \frac{1}{2} \bar{\chi}_L \gamma_\mu \boldsymbol{\tau} \chi_L, \quad j_\mu^Y = 2j_\mu^{em} - 2j_\mu^3$$

$$-i \left[g_w \mathbf{j}_\mu \cdot \mathbf{W}^\mu + \frac{g'}{2} j_\mu^Y B^\mu \right]$$

Electroweak Unification

Physical W^\pm bosons are charged combinations of **W** components

$$W_\mu^\pm \equiv \frac{1}{\sqrt{2}} (W_\mu^1 \mp i W_\mu^2)$$

Physical Z and γ (A_μ) are combinations of neutral **W** component and B_μ related by the “weak mixing angle” θ_w (where $\cos \theta_w = M_W/M_Z$)

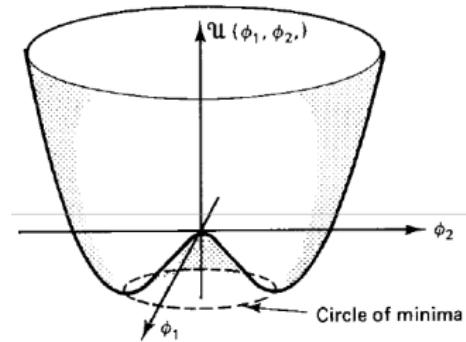

$$A_\mu = B_\mu \cos \theta_w + W_\mu^3 \sin \theta_w, \quad Z_\mu = -B_\mu \sin \theta_w + W_\mu^3 \cos \theta_w$$

The electromagnetic and weak interactions are both the result of an $SU(2)_L \otimes U(1)$ symmetry; the experimental force carriers are rotations of the vector bosons that couple to separate components of the weak isospin/hypercharge space, and the CP-violating nature of the weak interaction is a direct consequence of this construction as well.

The Higgs Mechanism

- ▶ Add a potential to a Lagrangian with a spontaneously broken continuous symmetry

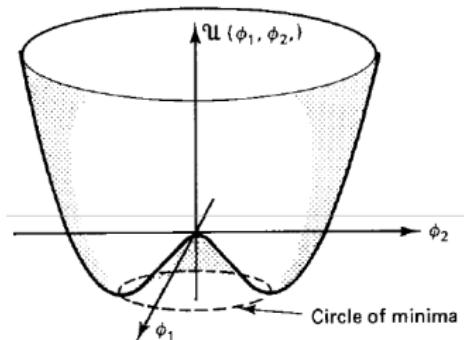

$$U = -\frac{1}{2}\mu^2(\phi_1^2 + \phi_2^2) + \frac{1}{4}\lambda^2(\phi_1^2 + \phi_2^2)^2$$

The Higgs Mechanism

$$U = -\frac{1}{2}\mu^2(\phi_1^2 + \phi_2^2) + \frac{1}{4}\lambda^2(\phi_1^2 + \phi_2^2)^2$$

- ▶ Add a potential to a Lagrangian with a spontaneously broken continuous symmetry
- ▶ Find minima of the potential to apply Feynman calculus

choose $\phi_{1,min} = \mu/\lambda$, $\phi_{2,min} = 0$

The Higgs Mechanism

- ▶ Add a potential to a Lagrangian with a spontaneously broken continuous symmetry
- ▶ Find minima of the potential to apply Feynman calculus
- ▶ Rewrite Lagrangian in terms of minimized coordinates

define $\eta \equiv \phi_1 - \mu/\lambda$, $\xi \equiv \phi_2$

$$\mathcal{L} = \left[\frac{1}{2}(\partial_\mu \eta)(\partial^\mu \eta) - \mu^2 \eta^2 \right] + \left[\frac{1}{2}(\partial_\mu \xi)(\partial^\mu \xi) \right] - \left[\mu \lambda (\eta^3 + \eta \xi^2) + \frac{\lambda^2}{4} (\eta^4 + \xi^4 + 2\eta^2 \xi^2) \right] + \frac{\mu^4}{4\lambda^2}$$

The Higgs Mechanism

- ▶ Add a potential to a Lagrangian with a spontaneously broken continuous symmetry
- ▶ Find minima of the potential to apply Feynman calculus
- ▶ Rewrite Lagrangian in terms of minimized coordinates
- ▶ Massive and massless ("Goldstone") scalar bosons emerge

define $\eta \equiv \phi_1 - \mu/\lambda$, $\xi \equiv \phi_2$

$$\mathcal{L} = \left[\frac{1}{2}(\partial_\mu \eta)(\partial^\mu \eta) - \mu^2 \eta^2 \right] + \left[\frac{1}{2}(\partial_\mu \xi)(\partial^\mu \xi) \right] - \left[\mu \lambda (\eta^3 + \eta \xi^2) + \frac{\lambda^2}{4} (\eta^4 + \xi^4 + 2\eta^2 \xi^2) \right] + \frac{\mu^4}{4\lambda^2}$$

The Higgs Mechanism

$$\begin{aligned}
 \mathcal{L} = & \left[\frac{1}{2} (\partial_\mu \eta)(\partial^\mu \eta) - \mu^2 \eta^2 \right] + \left[\frac{1}{2} (\partial_\mu \xi)(\partial^\mu \xi) \right] \\
 & + \left[-\frac{1}{16\pi} F^{\mu\nu} F_{\mu\nu} + \boxed{\frac{1}{2} \left(\frac{q}{\hbar c} \frac{\mu}{\lambda} \right)^2 A_\mu A^\mu} \right] - 2i \left(\frac{\mu}{\lambda} \frac{q}{\hbar c} \right) (\partial_\mu \xi) A^\mu \\
 & + \left\{ \frac{q}{\hbar c} [\eta(\partial_\mu \xi) - \xi(\partial_\mu \eta)] A^\mu + \frac{\mu}{\lambda} \left(\frac{q}{\hbar c} \right)^2 \eta (A_\mu A^\mu) + \frac{1}{2} \left(\frac{q}{\hbar c} \right)^2 (\xi^2 + \eta^2) (A_\mu A^\mu) \right. \\
 & \quad \left. - \lambda \mu (\eta^3 + \eta \xi^2) - \frac{1}{4} \lambda^2 (\eta^4 + 2\eta^2 \xi^2 + \xi^4) \right\} + \left(\frac{\mu^2}{2\lambda} \right)^2
 \end{aligned}$$

Applying this language to a complex field and demanding local gauge invariance yields a massive scalar (The “Higgs Boson”), and a *massive* vector boson

The Higgs Mechanism is the method by which the Z and W^\pm bosons acquire masses

The Higgs Mechanism (conceptually)

- ▶ Particles interact with the photon field in a way proportional to their charge
- ▶ The photon is an excitation of the EM field
- ▶ Particles interact with the Higgs field in a way proportional to their mass
- ▶ The Higgs Boson is an excitation of the Higgs field
- ▶ The Higgs field spontaneously breaks electroweak symmetry, giving mass to the W^\pm and Z bosons that interact with it
- ▶ Fermions gain their bare mass from the Higgs field, but not by EWSB

The Standard Model, Mathematically

- ▶ Begin with spinor fermions (ψ), vector gauge bosons (\mathbf{W}/B) and gluons (G_a), and scalar Higgs field (ϕ)
- ▶ Total symmetry group is $SU(3)_{color} \otimes SU(2)_L \otimes U(1)_Y$
- ▶ 19 known input parameters :
 - ▶ 9 quark/charged lepton masses
 - ▶ 3 CKM mixing angles and 1 CP-violating phase
 - ▶ $SU(3)$, $SU(2)$, and $U(1)$ gauge coupling strengths
 - ▶ QCD “vacuum angle”
 - ▶ Higgs VEV and mass
- ▶ With neutrinos, 7 others :
 - ▶ 3 masses
 - ▶ 4 PMNS matrix parameters
- ▶ Before spontaneous EWSB :
 - ▶ massless Higgs doublet
 - ▶ massless chiral fermions
 - ▶ massless gauge bosons (3 V-A)
- ▶ After spontaneous EWSB :
 - ▶ massive Higgs boson
 - ▶ massive fermions of mixed chiralities
 - ▶ massive Weak carriers (2 V-A)
 - ▶ massless photon

The Standard Model of Particle Physics

Spin 0 (Higgs Boson)

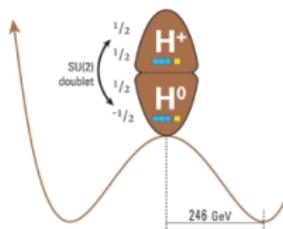

Hypercharge $\rightarrow Y$
 Weak Isospin $\rightarrow T_3$
 Gauge boson coupling
 H_0 mass (GeV)
 Electric Charge $Q = Y + T_3$

Spin 1/2 (Fermions)

Hypercharge (L) $\rightarrow Y$
 Weak Isospin (L) $\rightarrow T_3$
 Gauge boson coupling
 $\frac{1}{2}$ flavor
 Q
 Electric Charge $Q = Y + T_3$

Spin 1 (Gauge Bosons)

Fermion coupling
 \square symbol
 mass (GeV)

CERN

Physics Objects in the CMS Detector

Antisymmetric Event Reweighting

New tree-level $q\bar{q}$ cross section with antisymmetric extension:

$$\frac{d\sigma}{dc^*}(q\bar{q}; M^2) = R \frac{\pi \alpha_s^2}{9M^2} \beta \left\{ 1 + \beta^2 c^{*2} + (1 - \beta^2) + A_{FB}^{(1)} 2 \left[1 + \frac{1}{3} \beta^2 + (1 - \beta^2) \right] c^* \right\}$$

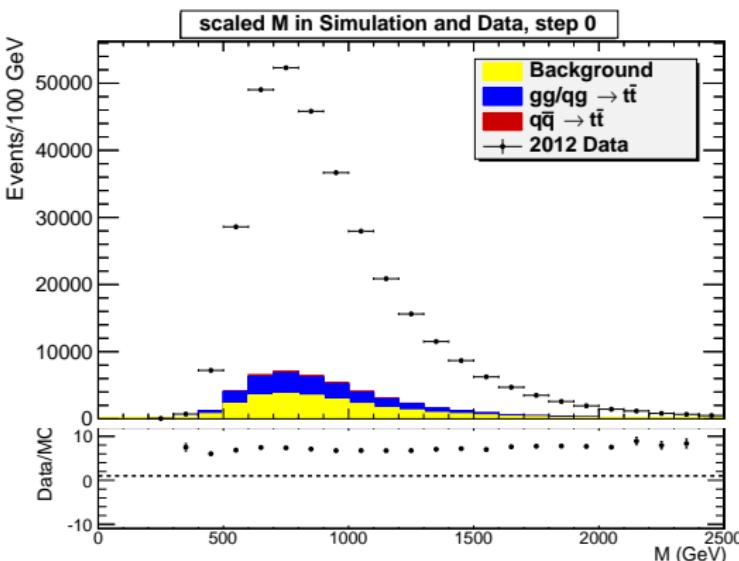

Means the antisymmetric distribution with $A_{FB}^{(1)}$ factored out can be built from the symmetric one by multiplying by an event weight w_a :

$$w_a(M^2, c^*) = 2 \frac{1 + \frac{1}{3} \beta^2 + (1 - \beta^2)}{1 + \beta^2 c^{*2} + (1 - \beta^2)} c^*$$

Therefore no special Monte Carlo simulation required to describe effect!

Event Selection

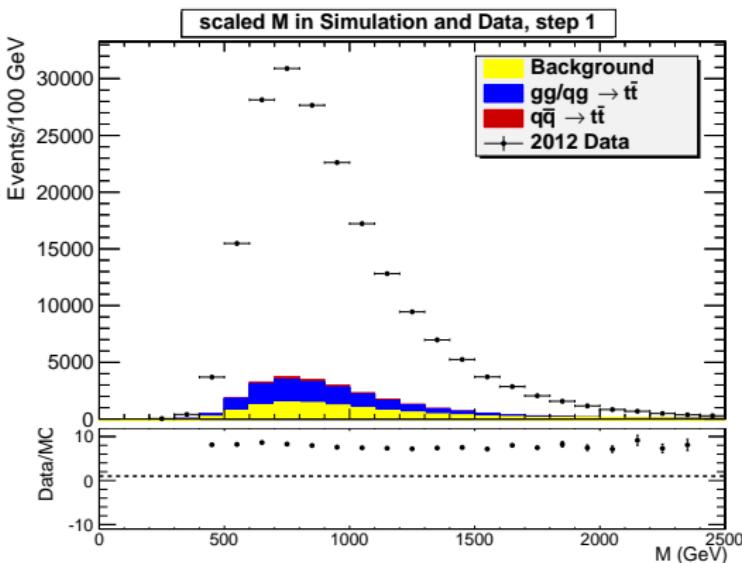

- ▶ Preselection

signal: tau32	686	0.268(4)	0.09(1)	0.20(1)	0.049(4)	0.034(7)	0.17(2)
full selection	488	0.064(1)	0.012(2)	0.013(1)	0.0036(4)	0.003(1)	0.014(2)

- Preselection removes events across the board without a boosted hadronic top
- muon ID is very efficient
- 2D cut is effective at removing events that lack a distinctive muon
- leptonic top mass cut is very effective
- pretagging leaves mostly top events and multijet background
- NTMJ statistics in the final signal region are expected to be very very small

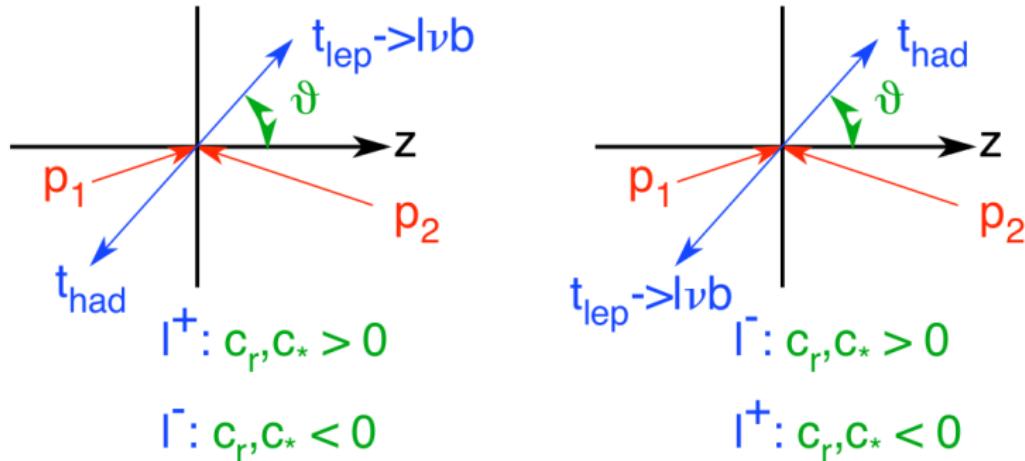

Cutflow (electrons)

full selection	179	0.049(1)	0.007(1)	0.0003(1)	0.0015(3)	0.004(1)	0.014(2)

- Electron ID is much less efficient than muon ID
- Pretagging is also slightly less efficient
- Everything else is comparable between the two channels

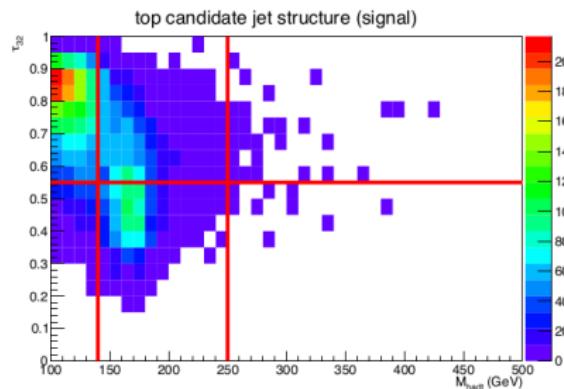

Exploiting CP symmetry

When separating events and templates by lepton charge, CP symmetry can be exploited to add each event with a symmetric initial state to two templates at once by conjugating lepton charge and flipping the sign of c^*

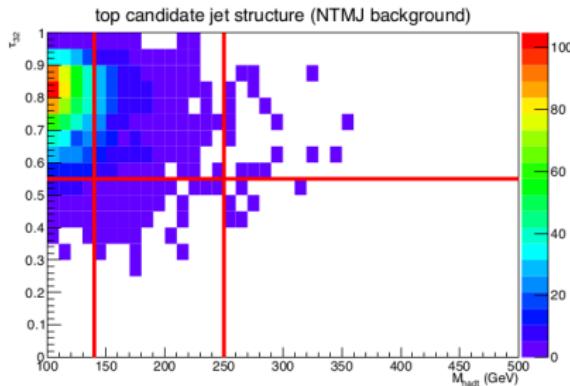

This increases statistics in F_{gg} templates and forces the absolute symmetry/antisymmetry of the F_{qs} and F_{qa} templates

Data-Driven NTMJ background estimation

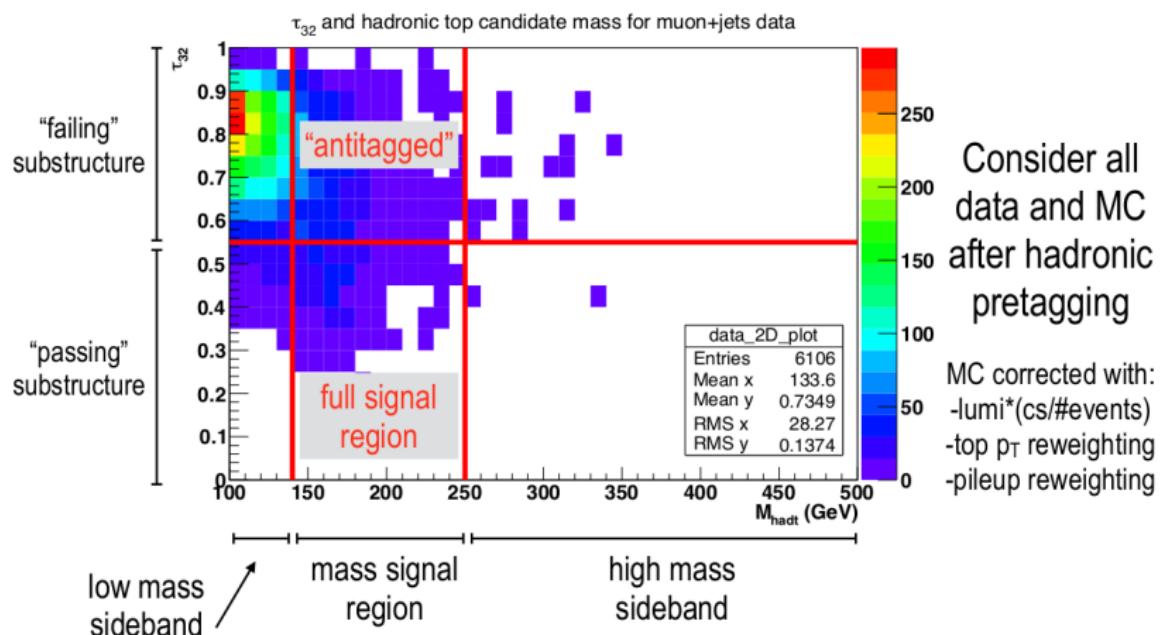

← Semileptonic ttbar
(simulated)

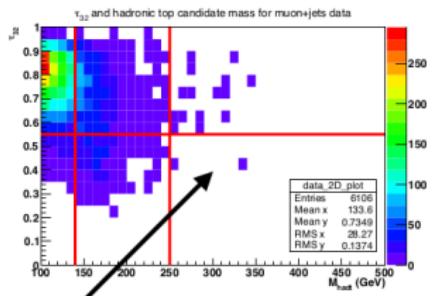

W/Z/gamma+jets
(simulated)

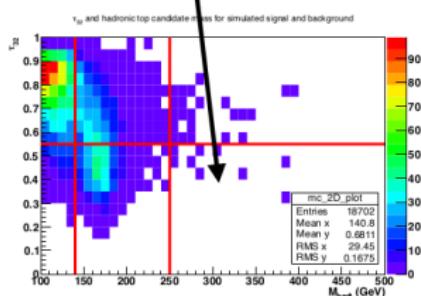

Data-Driven NTMJ background estimation

Data-Driven NTMJ background estimation

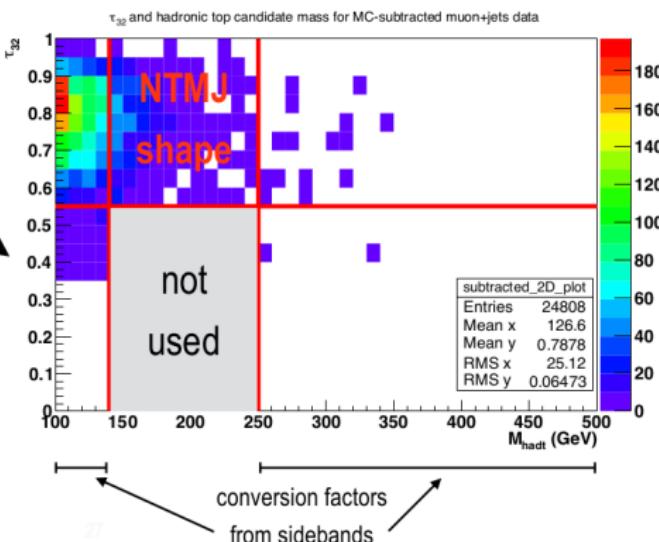

$$\text{data} - \text{MC} = \text{NTMJ}$$

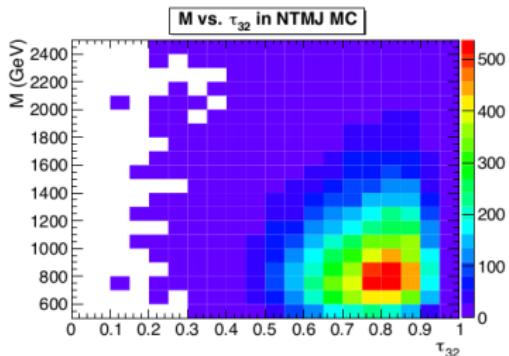

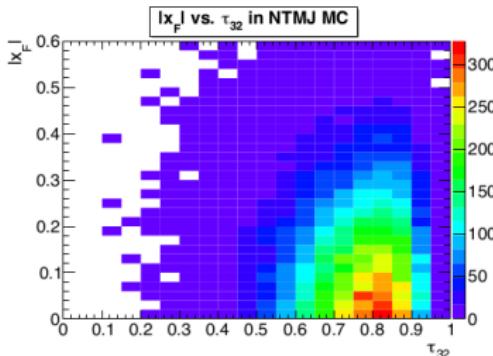

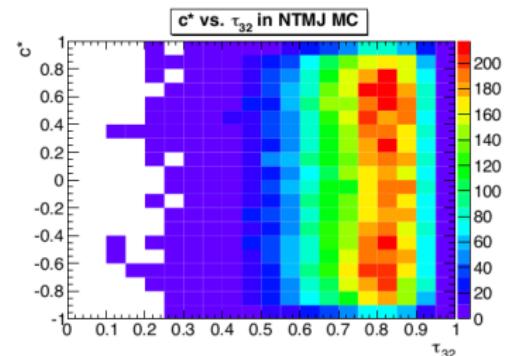

subtract MC from data in the antitagged region to get the NTMJ background shape

nominal normalization comes from interpolating conversion factors in mass sidebands

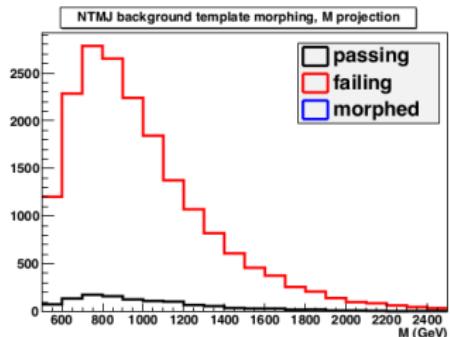

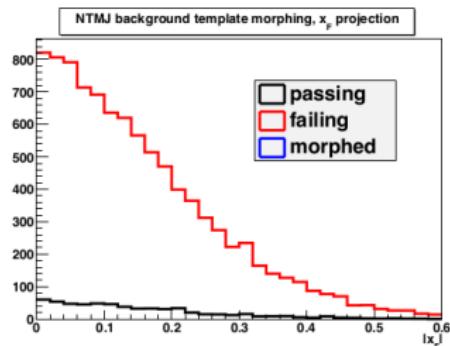

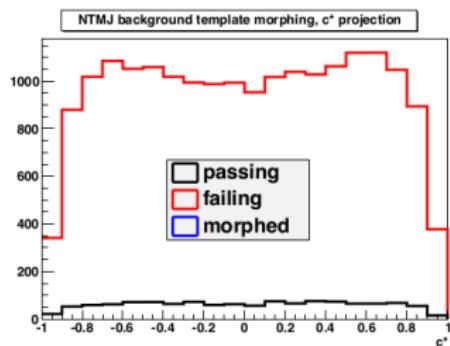

Data-Driven NTMJ background estimation

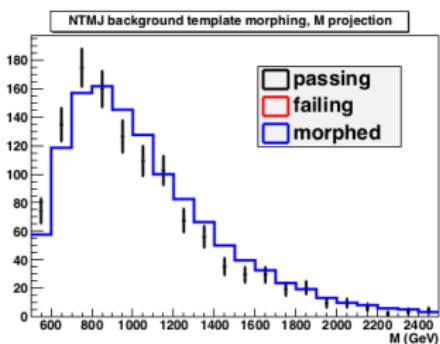

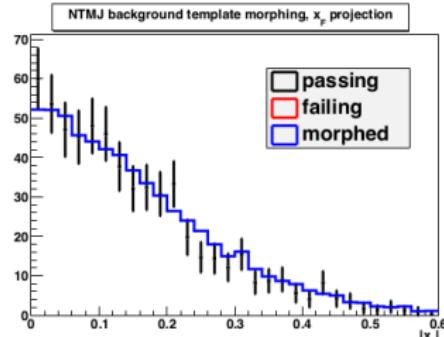

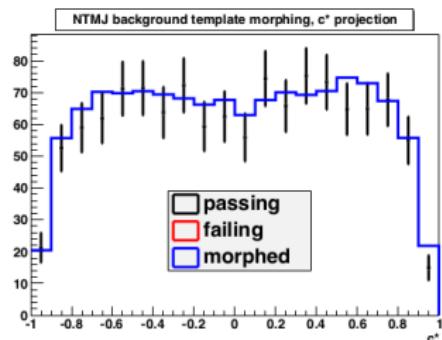

- NTMJ MC pictured after light skimming: statistics are only a problem in the full selection region
- No obvious dependence of any observable on τ_{32}
- Check that morphed shape from failing region looks like the simulated shape in the passing region

Data-Driven NTMJ background estimation

- Many more events fail the cut than pass as expected for background
- Shapes are close but need a scale factor

Data-Driven NTMJ background estimation

- Applying hadronic top candidate mass-dependent scale factor brings shapes and event yields more in line
- Morphing the templates in the failing region describes simulated events in the passing region well
- Systematics of morphing function are likely a small effect

Systematics

1. Jet Energy Corrections

- ▶ Jet Energy Scale (corrects measured jet energies to values seen in data)
- ▶ Jet Energy Resolution (smears jet angular and p_T distributions to values seen in data)

2. Pileup reweighting

- ▶ Morphs generated pileup values to look like that measured in data

3. Top pT reweighting

- ▶ low p_T (corrects generated top cross section to NNLO prediction)
- ▶ high p_T (corrects generated top cross section to measurement in data)

4. Lepton ID and trigger efficiencies

- ▶ Correct for differences in efficiencies in data/MC
- ▶ Used accepted values for muons, measured for electrons

5. Luminosity (uncertainty on total luminosity is $\approx 2.6\%$)

6. PDF systematics (PDF choice parameterized by many values with uncertainties)

7. Finite Monte Carlo Statistics

Measuring Electron ID efficiency

- Using a simple muon pT trigger in the muon+jets channel
 - HLT_Mu40_eta2p1_v*
- electron+jets channel isn't as clean: choose a trigger with jet requirements
 - HLT_Ele30_CaloIdVT_TrkIdT_PFNoPUJet100_PFNNoPUJet25_v*
- These two triggers are independent
- Measure electron trigger efficiency in e/mu dileptonic ttbar events

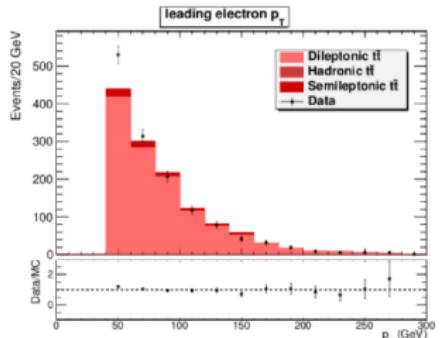

Measuring Electron ID efficiency

- Events must fire muon trigger
- Select leading muon and electron:
 - Loosely ID'd (isLoose for muons, "isPseudoLoose" for electrons)
 - $P_T > 40 \text{ GeV}$, $|\eta| < 2.4$
 - 2D cut for "isolation": $p_{T,\text{rel}} > 25 \text{ GeV}$ or $\Delta R_{\text{nearest jet}} > 0.5$
- Veto events with any additional leptons passing the above

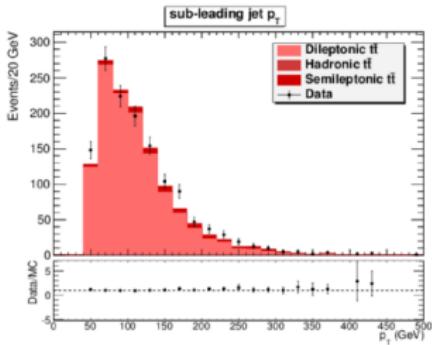

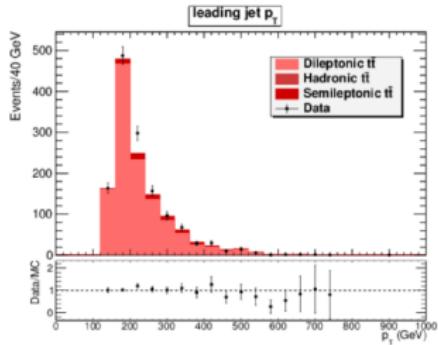

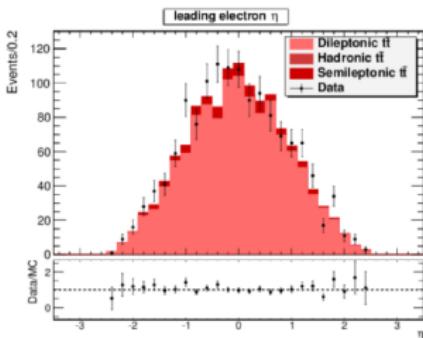

Measuring Electron ID efficiency

- Additional leptonic side criteria
 - Leading e/mu have opposite charges
 - leptonic W $p_T > 50$ GeV
 - leptonic top mass in $140 < M_{t\bar{t}lep} < 250$ GeV
- Require at least two jets with $p_T > 150$ and 50 GeV respectively
- Resulting events are clean e/mu dileptonic ttbar
- Will measure efficiency for these events to also fire the electron trigger in data and ttbar MC

Measuring Electron ID efficiency

- MC scaled by Lumi and CS
- Pileup reweighting applied
- Generally good agreement
- Very little data unaccounted for by ttbar

Measuring Electron ID efficiency

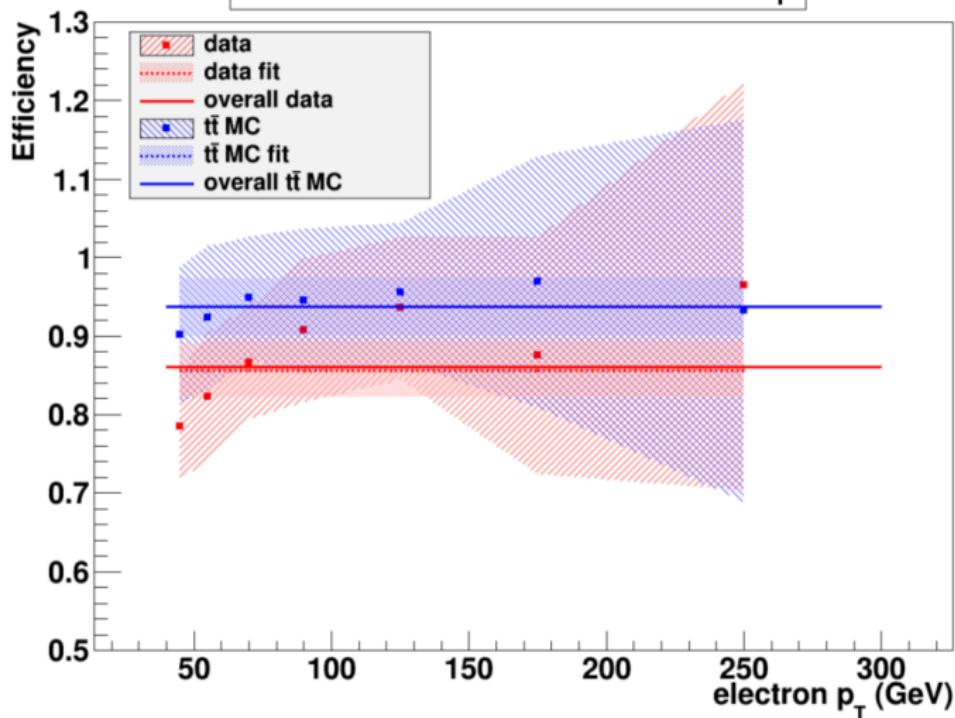

- Data events selected = 1364
- Data events passing trigger = 1174
- Efficiency in data = 0.86 ± 0.03
- MC events selected = 5750 (1290 scaled)
- MC events passing trigger = 5389 (1218 scaled)
- Efficiency in MC = 0.94 ± 0.04
- Data/MC Scalefactor = 0.92 ± 0.05

Measuring Electron ID efficiency

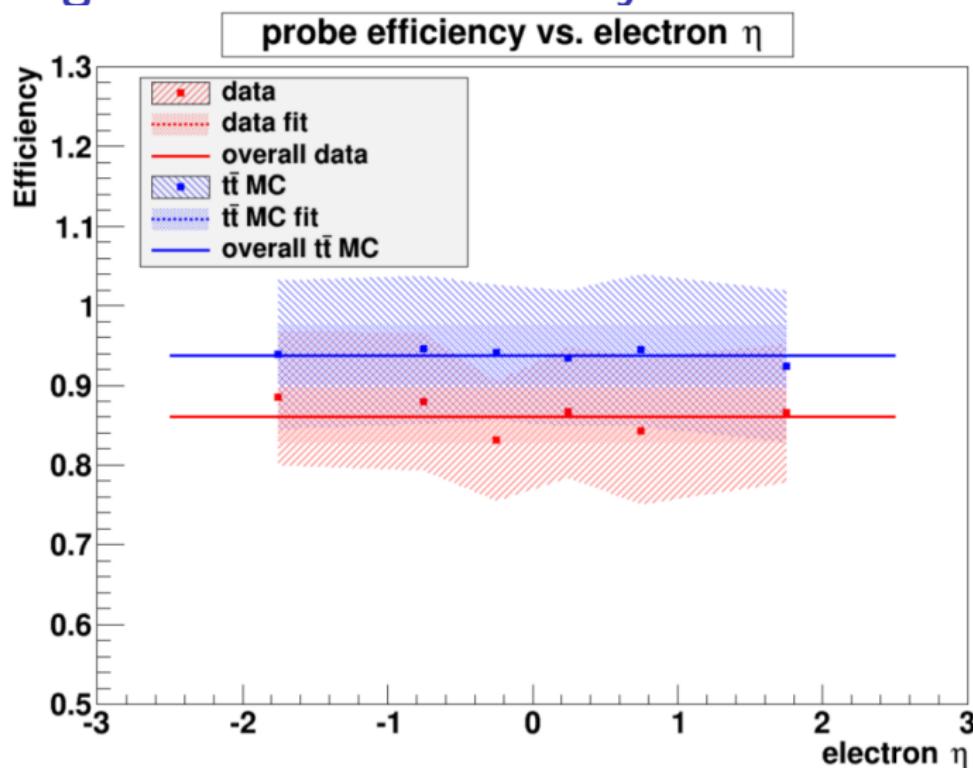

- Data/MC Scalefactor = 0.92 ± 0.05
- All errors statistical only
- Correction applied to all MC as simple nominal/up/down scalefactors
- No significant dependence on phase space (checked electron kinematics and jet p_T because of jet involvement in trigger)

Measuring Electron ID efficiency

probe efficiency vs. electron p_T

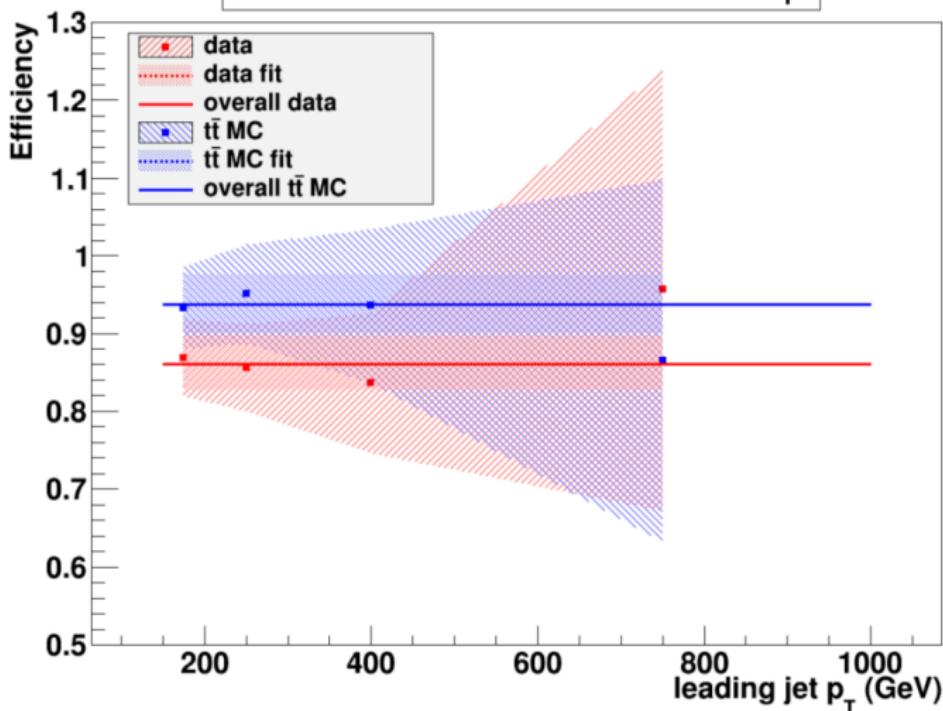

Measuring Electron ID efficiency

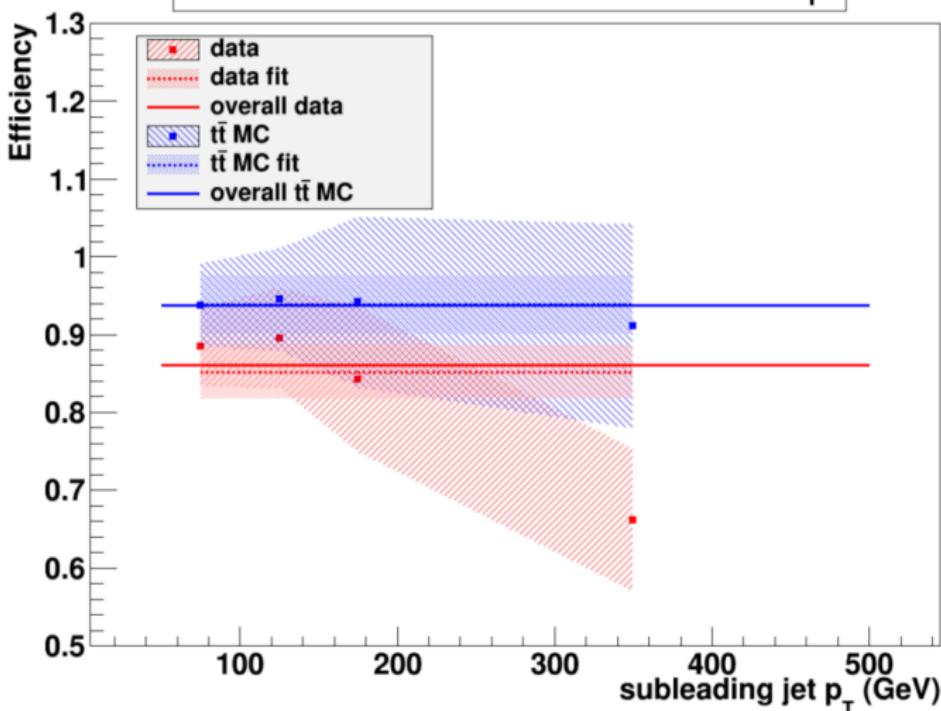

Measuring Electron ID efficiency

probe efficiency vs. leading jet p_T

Measuring Electron ID efficiency

probe efficiency vs. subleading jet p_T

Measuring Electron Trigger efficiency

- In the boosted lepton+jets channel we're not expecting an isolated lepton
- Most versions of ID used are informed by isolation for electrons
 - Cut-based (“isLoose”, “isTight”) has a cut on PFIso
 - MVA ID is calculated partially using isolation
 - MVA ID working points are also paired with companion cuts on PFIso in practice
- We're using cut-based “isLoose” but with the isolation requirement explicitly bypassed (“isPseudoLoose”)

Measuring Electron Trigger efficiency

- This isolation has no published scalefactors so we measure the efficiency in data and MC using a tag-and-probe method
- Tags are clear electrons from a leptonic top
- Probes are other kinematically valid electrons
- We make additional cuts to examine mostly $t\bar{t}$ → $e^+/e^- + \text{jets}$ events, and test the efficiency for probe electrons to pass our selection

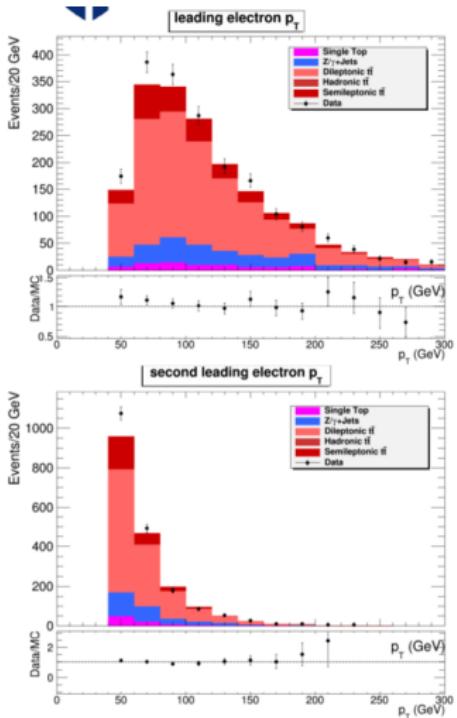

Measuring Electron Trigger efficiency

- Tag Selection:
 - Electron passing “isPseudoLoose”
 - With $p_T > 40 \text{ GeV}$, $|\eta| < 2.4$, passing 2D cut
 - Reconstructed W $p_T > 50 \text{ GeV}$
- Probe Selection:
 - Second electron with $p_T > 40 \text{ GeV}$, $|\eta| < 2.4$, passing 2D cut
- Veto events with any valid muons passing “isLoose” with the same kinematic requirements as above

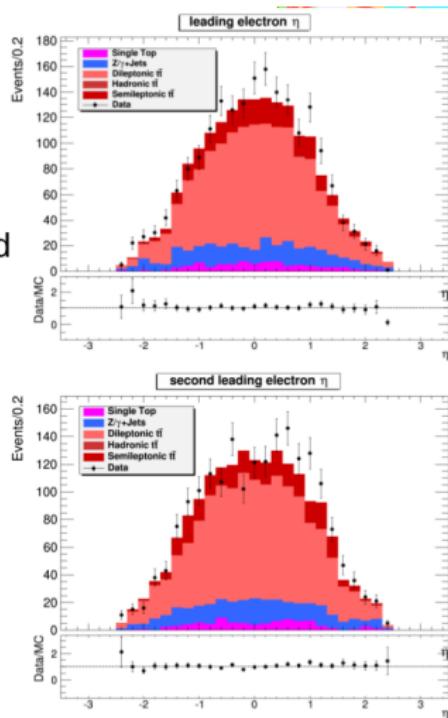

Measuring Electron Trigger efficiency

- Also require the two electrons to have opposite charges
- Cut on combined e^+e^- mass M_{ee}
 - $M_{ee} > 12$ GeV to legitimize dilepton topology
 - M_{ee} outside Z-mass window (76-106 GeV) to reject $Z + \text{jets} \rightarrow e^+e^- + \text{jets}$ events
- Hadronic cuts
 - At least two jets with $p_T > 150, 50$ GeV respectively
 - At least one loose btag (using CSV tagger with loose working point)

Measuring Electron Trigger efficiency

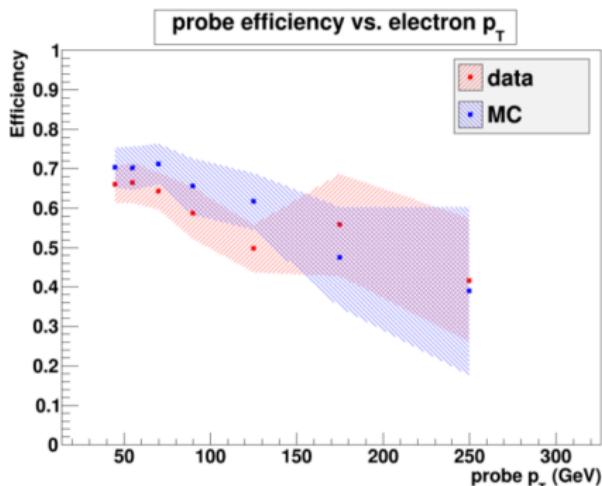

- Not as clean as e/mu selection for trigger
- More MC used to account for data (Z+jets and single top added)
- Still missing something (probably QCD) but description isn't terrible

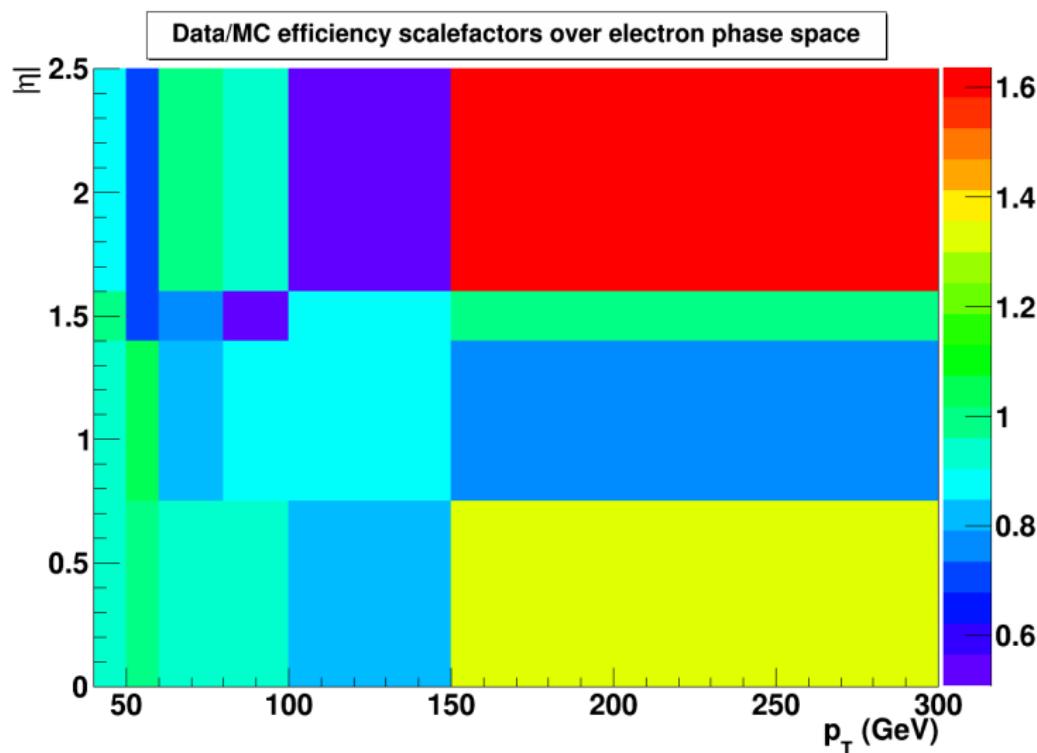

Measuring Electron Trigger efficiency

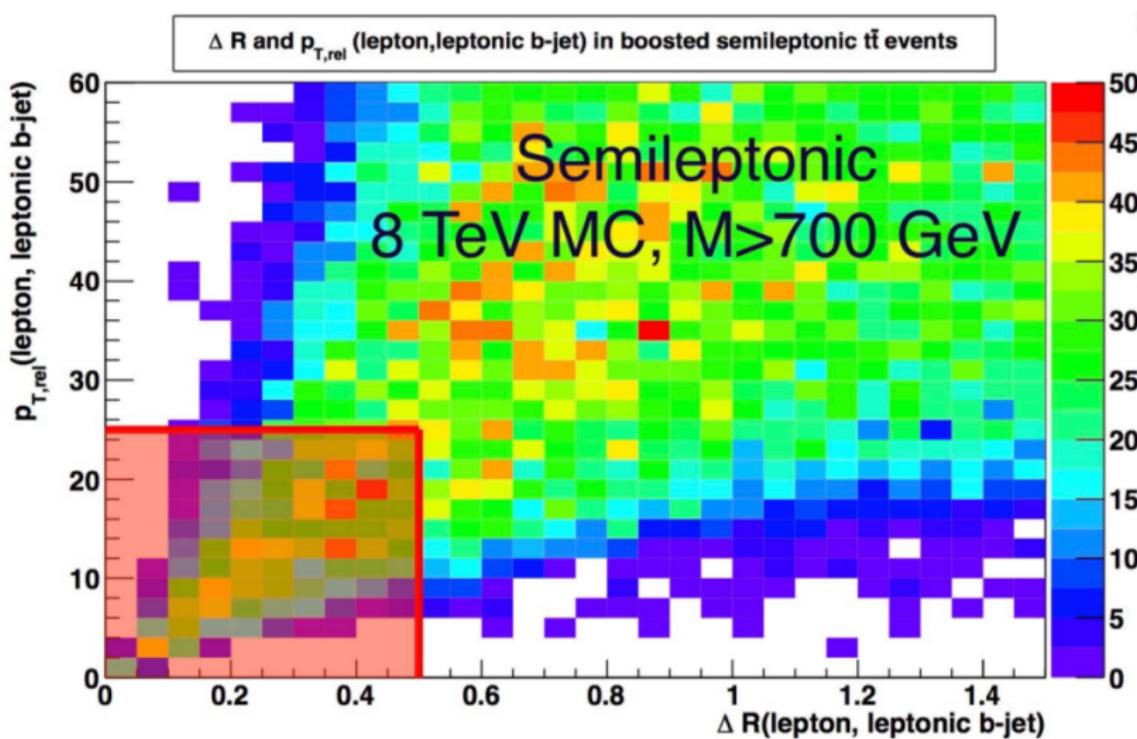

- 1943 tag/probe pairs in data
- 8842 (1812 scaled) pairs in MC
- Generally lower efficiency than seen for standard $Z \rightarrow e^+e^-$ -tag-and-probe measurements
 - Maybe due to boosting?
 - Maybe due to choice of ttbar?
 - Regardless these events look more like those in our analysis
- Strong dependence of efficiency on probe electron parameters
- Dependence consistent between MC and data
- Apply scalefactors that vary over electron phase space

Measuring Electron Trigger efficiency

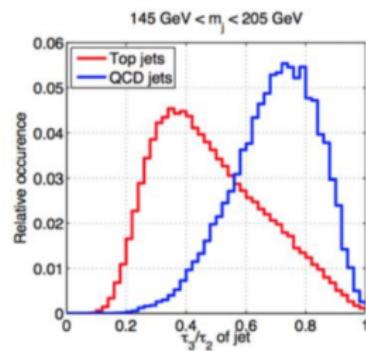

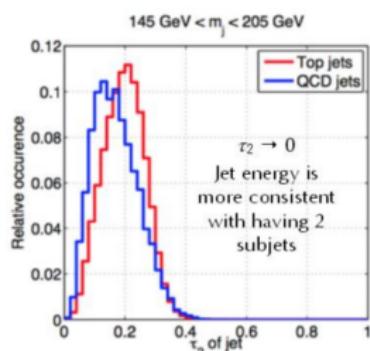

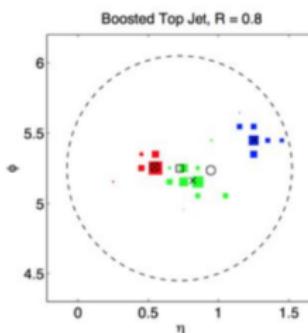

Boosted lepton “Isolation”: 2D cut

Jet Substructure: N-subjettiness

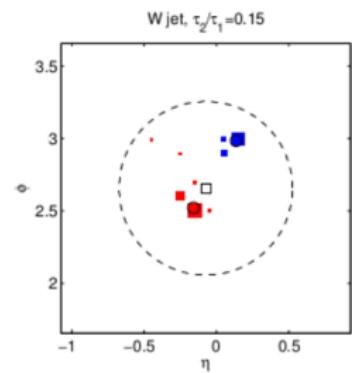

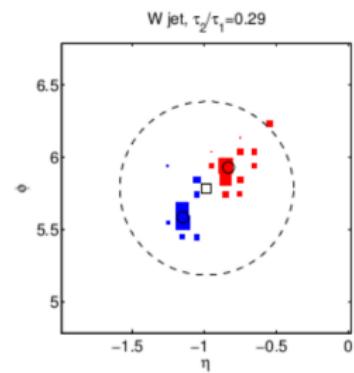

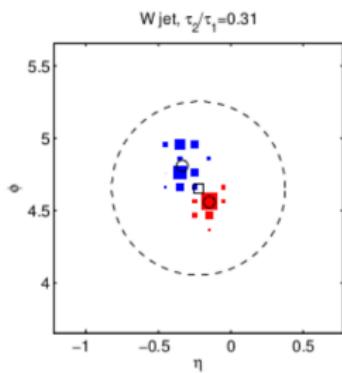

- A low τ_n means a jet is more consistent with n subjets
- Merged top jet should have three subjets
 - Cut on τ_3 / τ_2

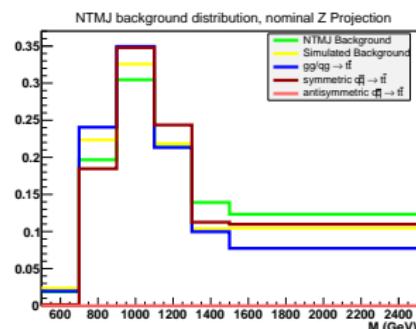

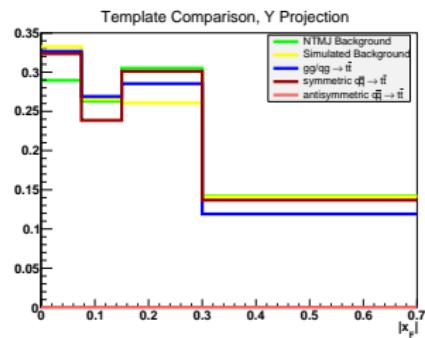

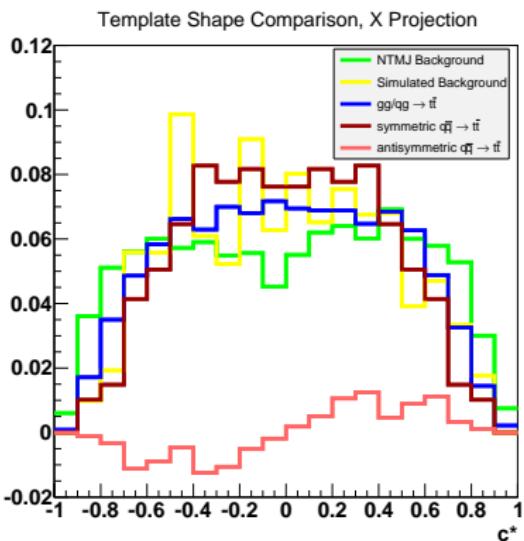

Plots From James Dolen: JetMET Algorithms and Reconstruction Meeting - June 6, 2013

Jet Substructure: N-subjettiness

$$\tau_{N_2N_1} = \frac{\sum_k p_{T,k} \min [\Delta R_{1,k}, \dots, \Delta R_{N_2,k}]}{\sum_k p_{T,k} \min [\Delta R_{1,k}, \dots, \Delta R_{N_1,k}]}$$

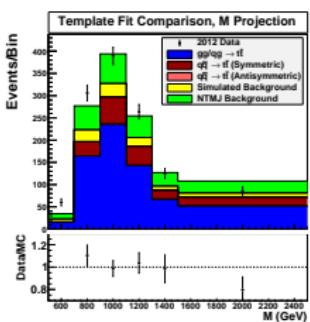

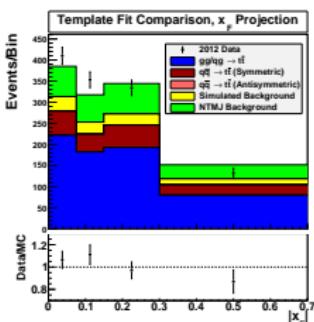

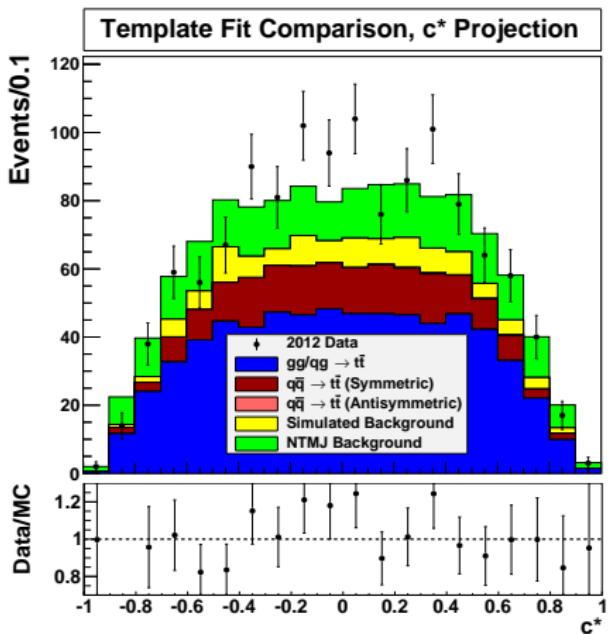

Template Shape Comparison

Events added to 3D histograms
 $F_{q\bar{q}s}/F_{q\bar{q}a}$ distributions
 symmetrized/antisymmetrized

Template Fit Results

Result: $A_{FB} = 7.9\% \pm 7.7\%$
